NEW ZEALAND DATA SHEET

Amlodipine [Ethics]
Tablets, Amlodipine Besylate Ph Eur, 5 mg and 10 mg (as amlodipine)

Presentation
Amlodipine [Ethics] 5 mg
White to off white, octagonal shaped, uncoated tablets, debossed AM 5 on one face and scored on the obverse face. Each tablet contains Amlodipine Besylate Ph Eur equivalent to amlodipine 5 mg.

Amlodipine [Ethics] 10 mg
White to off white, octagonal shaped, uncoated tablets, debossed AM 10 on one face and plain on the obverse face. Each tablet contains Amlodipine Besylate Ph Eur equivalent to amlodipine 10 mg.

Uses
Pharmacotherapeutic group
C08CA01: member of C08CA - dihydropyridine derivatives, a subset of C08C – selective calcium channel blockers with mainly vascular effects.

Actions
Amlodipine is a calcium ion influx inhibitor (slow channel blocker or calcium ion antagonist) that inhibits the transmembrane influx of calcium ions into cardiac and vascular smooth muscle.

The mechanism of the antihypertensive action of amlodipine is due to a direct relaxant effect on vascular smooth muscle.

The precise mechanism by which amlodipine relieves angina has not been fully determined but amlodipine reduces total ischaemic burden by the following two actions. (1) Amlodipine dilates peripheral arterioles and thus reduces the total peripheral resistance (afterload) against which the heart works. Since the heart rate remains stable, this unloading of the heart reduces myocardial energy consumption and oxygen requirements. (2) The mechanism of action of amlodipine also probably involves dilatation of the main coronary arteries and coronary arterioles, both in normal and ischaemic regions. This dilatation increases myocardial oxygen delivery in patients with coronary artery spasm (Prinzmetal's or variant angina) and blunts smoking induced coronary vasoconstriction.

In patients with hypertension, once daily dosing provides clinically significant reductions of blood pressure in both the supine and standing positions throughout the 24 hour interval.

Due to the slow onset of action, acute hypotension is not a feature of amlodipine administration.

In patients with angina, once daily administration of amlodipine increases total exercise time, time to angina onset and time to 1 mm ST segment depression, and decreases both angina attack frequency and nitroglycerine tablet consumption.
Amlodipine [Ethics]
Tablets, Amlodipine Besylate Ph Eur, 5 mg and 10 mg (as amlodipine)

Use in patients with heart failure

Haemodynamic studies and exercise based controlled clinical trial in NYHA Class II-IV heart failure patients have shown that amlodipine did not lead to clinical deterioration as measured by exercise tolerance, left ventricular ejection fraction and clinical symptomatology.

A placebo-controlled study (PRAISE) designed to evaluate patients with NYHA Class III-IV heart failure receiving digoxin, diuretics, and angiotensin converting enzyme (ACE) inhibitors has shown that amlodipine did not lead to an increase in risk of mortality or combined mortality and morbidity in patients with heart failure.

In a follow-up, long-term, placebo controlled study (PRAISE-2) of amlodipine in patients with NYHA III and IV heart failure without clinical symptoms or objective findings suggestive of underlying ischaemic disease, on stable doses of ACE inhibitors, digitalis and diuretics, amlodipine had no effect on total cardiovascular mortality. In this same population, amlodipine was associated with increased reports of pulmonary oedema despite no significant difference in the incidence of worsening heart failure as compared to placebo (refer to Warnings and precautions).

Amlodipine has not been associated with any adverse metabolic effects or changes in plasma lipids and is suitable for use in patients with asthma, diabetes and gout.

Pharmacokinetics

Absorption
Amlodipine is well absorbed orally with peak blood levels occurring 6 to 12 hours post-dose. Oral administration of a single therapeutic dose gave a mean absolute bioavailability of 64% (range 52 to 88%). The absorption of amlodipine is unaffected by consumption of food.

Distribution
The volume of distribution is approximately 20 L/kg. In vitro studies have shown that approximately 97.5% of circulating amlodipine is bound to plasma proteins.

Biotransformation
Amlodipine is extensively metabolised by the liver to inactive metabolites with 10% of the parent compound and 60% of metabolites excreted in the urine.

Elimination
The terminal plasma elimination half-life is about 35 to 50 hours and is consistent with once daily dosing. Steady state plasma levels are attained after 7 to 8 days of consecutive dosing.

Amlodipine is not dialysable.

Indications
Amlodipine is indicated for the first line treatment of hypertension and can be used as the sole agent to control blood pressure in the majority of patients. Patients not adequately controlled on a single antihypertensive agent may benefit from the addition of amlodipine, which has been used in combination with a thiazide diuretic, beta-adrenoceptor blocking agent, or an angiotensin-converting enzyme inhibitor.
Amlodipine [Ethics]
Tablets, Amlodipine Besylate Ph Eur, 5 mg and 10 mg (as amlodipine)

Amlodipine is indicated for the first line treatment of myocardial ischaemia, whether due to fixed obstruction (stable angina) and/or vasospasm/vasoconstriction (Prinzmetal's or variant angina) of coronary vasculature. Amlodipine may be used where the clinical presentation suggests a possible vasospastic/vasoconstrictive component but where vasospasm/vasoconstriction has not been confirmed. Amlodipine may be used alone as monotherapy, or in combination with other antianginal medicines in patients with angina that is refractory to nitrates and/or beta blockers.

Dosage and administration
For both hypertension and angina, the usual initial dose is amlodipine 5 mg once daily which may be increased to a maximum dose of 10 mg depending on the individual patient's response.

No dose adjustment of amlodipine is required upon concomitant administration of thiazide diuretics, beta blockers and angiotensin-converting enzyme inhibitors.

Use in the elderly
The time to reach peak plasma concentrations of amlodipine is similar in elderly and younger subjects. Amlodipine clearance tends to be decreased with resulting increases in AUC and elimination half-life in elderly patients.

Increases in AUC and elimination half-life in patients with congestive heart failure were as expected for the patient age group studied.

Amlodipine, used at similar doses in elderly or younger patients, is equally well tolerated. Therefore normal dosage regimens are recommended.

Use in renal disease
Amlodipine is extensively metabolised to inactive metabolites with 10% excreted as unchanged medicine in the urine. Changes in amlodipine plasma concentrations are not correlated with degree of renal impairment. Amlodipine may be used in such patients at normal doses. Amlodipine is not dialysable.

Use in children
Amlodipine is not recommended for use in children.

Contraindications
Amlodipine is contraindicated in patients with a known sensitivity to amlodipine, dihydropyridines or any of the listed inactive ingredients.

Warnings and precautions
Use in patients with heart failure
In a long term placebo-controlled study (PRAISE-2) of amlodipine in patients with NYHA III and IV heart failure of nonischaemic aetiology, amlodipine was associated with increased reports of pulmonary oedema despite no significant difference in the incidence of worsening heart failure as compared to placebo (refer to Uses, Use in patients with heart failure).
Pregnancy and lactation

Assigned Category C in the Australian Categorisation of risk system. Category C refers to medicines which, owing to their pharmacological effects, have caused or may be suspected of causing, harmful effects on the human foetus or neonate without causing malformations. These effects may be reversible. Accompanying texts should be consulted for further details. Specifically, calcium channel blockers carry the potential to produce foetal hypoxia associated with maternal hypotension.

Safety of amlodipine in human pregnancy or lactation has not been established. Amlodipine did not demonstrate any foetotoxic nor teratogenic potential in animal reproductive studies other than to delay parturition and prolong labour in rats at a dose level fifty times the maximum recommended dose in humans. No mutagenic activity has been found in tests for gene mutations or cytogenic assays. Accordingly, use in pregnancy is recommended only when there is no safer alternative and when the disease itself carries greater risk for the mother and foetus.

Use in patients with impaired hepatic function

As with all calcium channel blockers, amlodipine half-life is prolonged in patients with impaired liver function and dosage recommendations have not been established. The compound should therefore be administered with caution in these patients.

Use in children

Safety and effectiveness of amlodipine in children have not been established.

Effects on ability to drive and use machinery

Clinical experience with amlodipine indicates that it is unlikely to impair a patient’s ability to drive or use machinery.

Adverse effects

Clinical trial data

Amlodipine is well-tolerated. In placebo controlled clinical trials involving patients with hypertension or angina, the most commonly observed adverse effects were headache, oedema, fatigue, somnolence, nausea, abdominal pain, flushing, palpitations and dizziness. In these clinical trials no pattern of clinically significant laboratory test abnormalities related to amlodipine has been observed.

Post-marketing surveillance data

Less commonly observed adverse effects in marketing experience include:

Rarely, allergic reactions including pruritus, rash, angioedema and erythema multiforme have been reported.

Hepatitis, jaundice and hepatic enzyme elevations have also been reported very infrequently (mostly consistent with cholestasis). Some cases severe enough to require hospitalisation have been reported in association with use of amlodipine. In many instances, causal association is uncertain.

As with other calcium channel blockers the following adverse events have been rarely reported and cannot be distinguished from the natural history of the underlying disease: myocardial infarction, arrhythmia (including bradycardia, ventricular tachycardia and atrial fibrillation) and chest pain.

**INTERACTIONS**
Amlodipine has been safely administered with thiazide diuretics, beta blockers, alpha blockers, angiotensin-converting enzyme inhibitors, long-acting nitrates, sublingual glyceryl trinitrate, non-steroidal anti-inflammatory agents, antibiotics, and oral hypoglycaemic agents.

**Plasma protein displacement**
*In vitro* data from studies with human plasma indicate that amlodipine has no effect on protein binding of the medicines tested (digoxin, phenytoin, warfarin, or indomethacin).

**Microsomal enzymes**
**CYP3A4 inhibitors**
With concomitant use with the CYP3A4 inhibitor erythromycin in young patients and diltiazem in elderly patients, the plasma concentration of amlodipine was increased. The clinical relevance of this finding is uncertain. It cannot be ruled out that strong inhibitors of CYP3A4 (e.g., ketoconazole, itraconazole, ritonavir) may increase the plasma concentrations...
Amlodipine [Ethics]
Tablets, Amlodipine Besylate Ph Eur, 5 mg and 10 mg (as amlodipine)

of amlodipine to a greater extent than diltiazem. Amlodipine should be used with caution together with CYP3A4 inhibitors.

CYP3A4 inducers
There are no data available regarding the effect of CYP3A4 inducers on amlodipine. The concomitant use of CYP3A4 inducers (e.g., rifampicin, Hypericum perforatum or St John’s Wort) may give a lower plasma concentration of amlodipine. Amlodipine should be used with caution together with CYP3A4 inducers.

Effect of other medicines on amlodipine

Cimetidine
Co-administration of amlodipine with cimetidine did not alter the pharmacokinetics of amlodipine.

Aluminium/Magnesium (antacid)
Co-administration of an aluminium/magnesium based antacids with a single dose of amlodipine had no significant effect on the pharmacokinetics of amlodipine.

Sildenafil
A single 100 mg dose of sildenafil in subjects with essential hypertension had no effect on the pharmacokinetic parameters of amlodipine. When amlodipine and sildenafil were used in combination, each agent independently exerted its own blood pressure lowering effect.

Effect of amlodipine on other medicines

Atorvastatin
Co-administration of multiple 10 mg doses of amlodipine with 80 mg of atorvastatin resulted in no significant change in the steady state pharmacokinetic parameters of atorvastatin.

Digoxin
Co-administration of amlodipine with digoxin did not change serum digoxin levels or digoxin renal clearance in normal volunteers.

Warfarin
Co-administration of amlodipine with warfarin did not change the warfarin prothrombin response time.

Cyclosporin
Pharmacokinetic studies with cyclosporin have demonstrated that amlodipine does not significantly alter the pharmacokinetics of cyclosporin.

Food and beverage

Grapefruit juice
Administration of amlodipine with grapefruit or grapefruit juice is not recommended as bioavailability may be increased in some patients resulting in increased blood pressure lowering effects.
Alcohol
Single and multiple 10 mg doses of amlodipine had no significant effect on the pharmacokinetics of ethanol.

OVERDOSAGE
Signs and symptoms
Available data suggest that gross overdosage could result in excessive peripheral vasodilatation and possibly reflex tachycardia. Marked and probably prolonged systemic hypotension up to and including shock with fatal outcome has been reported.

Treatment
Administration of activated charcoal to healthy volunteers immediately or up to two hours after ingestion of amlodipine 10 mg has been shown to significantly decrease amlodipine absorption. Gastric lavage may be worthwhile in some cases. Clinically significant hypotension due to amlodipine overdosage calls for active cardiovascular support including frequent monitoring of cardiac and respiratory function, elevation of extremities, and attention to circulating fluid volume and urine output. A vasoconstrictor may be helpful in restoring vascular tone and blood pressure, provided that there is no contraindication to its use. Intravenous calcium gluconate may be beneficial in reversing the effects of calcium channel blockade. Dialysis is not likely to be of benefit since amlodipine is highly protein bound.

PHARMACEUTICAL PRECAUTIONS
Store below 30°C. Protect from light.

MEDICINE CLASSIFICATION
Prescription Medicine

PACKAGE QUANTITIES
Blister strips of 100 tablets.

FURTHER INFORMATION
List of inactive ingredients
Microcrystalline cellulose, mannitol, magnesium stearate, sodium starch glycolate, colloidal anhydrous silica.
