CODEINE PHOSPHATE 15mg, 30mg & 60mg Tablets
Codeine Phosphate Hemihydrate BP

PRESENTATION

What it looks like

Codeine Phosphate Tablets are white, biconvex circular tablets.

USES

Actions
Codeine phosphate is an opioid analgesic with uses similar to those of morphine, but is much less potent as an analgesic and has only mild sedative effects. Its primary site of action is at the mu opioid receptors distributed throughout the central nervous system.

Codeine phosphate reduces intestinal motility through both a local and possibly central mechanism of action.

Codeine and its salts are absorbed from the gastro-intestinal tract and onset of analgesic action occurs 30 to 45 minutes after administration, when given orally.

Peak effect is reached within 1 to 2 hours and the duration of analgesic action is 4 hours.

Pharmacokinetics

Codeine is readily absorbed from the gastro-intestinal tract and metabolised by O- and N-demethylation in the liver to morphine and norcodeine which, with codeine, are excreted almost entirely by the kidney, mainly as conjugates with glucuronic acid.

Most of the excretion products appear in the urine within 6 hours and 40 to 60 percent of the codeine is excreted free or conjugated, approximately 5 to 15 percent as free and conjugated morphine and about 10 to 20 percent free and conjugated norcodeine.

Indications
Codeine phosphate is indicated for:

- the relief of mild to moderate pain (including pain associated with terminal illness, post-operative pain and headache),
- the relief of symptoms of diarrhoea (except diarrhoea caused by poisoning).

Codeine is particularly valuable for pain associated with coughing.

DOSAGE & ADMINISTRATION

Adults:

Codeine phosphate may be given orally in doses of 15mg – 60mg every 4 – 6 hours as needed.
If these doses fail to relieve pain, larger doses rarely succeed and may give rise to restlessness and excitement.

The maximum recommended daily dose is 300mg.

**Paediatric:**
The usual paediatric dose for infants and children is 0.5mg per kg of body weight or 15mg per square metre of body surface, every 4 to 6 hours as needed. The maximum recommended dose is 240 mg in 24 hours. The duration of treatment should not normally exceed 3 days.

Do not give to children aged less than 1 year.

Do not give to children aged less than 6 years with acute diarrhoea.

**CONTRAINDICATIONS**

Codeine phosphate is contraindicated in:

- Known hypersensitivity to codeine, other opioids or any component of the tablets
- Acute respiratory depression, especially in the presence of cyanosis and excessive bronchial secretion
- Obstructive airways disease
- Acute alcoholism
- Head injuries and conditions in which intracranial pressure is raised
- Patients at risk of paralytic ileus
- Hepatic failure
- Acute asthma attack
- Heart failure secondary to chronic lung disease
- Diarrhoea associated with pseudomembranous colitis or caused by poisoning
- Patients taking monoamine oxidase inhibitors or within fourteen days of stopping such treatment
- Children aged less than 1 year
- Young children aged less than 6 years with acute diarrhoea

**WARNINGS & PRECAUTIONS**
The following patients may be more susceptible to the effects of codeine. The lowest effective dose for the shortest period of time should be prescribed. Signs of toxicity or overdose may include nausea, vomiting, constipation, lack of appetite, somnolence, extreme sleepiness, confusion, shallow breathing and even coma. If symptoms of toxicity are present, codeine should be stopped immediately and medical advice sought.

- recent tonsillectomy, adenoidectomy or throat surgery
- hypothyroidism
- adrenocortical insufficiency e.g. Addison's disease
- impaired kidney or liver function
- prostatic hypertrophy
- shock/hypotension
- myasthenia gravis
- convulsions / convulsive disorders
- gall bladder disease or gall stones
- recent gastro-intestinal surgery
- urinary tract surgery
- reduced respiratory function or history of asthma
- obstructive bowel disorders – codeine reduces peristalsis, increases tone and segmentation in the bowel and can raise colonic pressure
- Patients taking monoamine oxidase inhibitors or within 14 days of stopping such treatment

**Hypersensitivity**

Maculopapular rash, fever, splenomegaly and lymphadenopathy have been seen as part of a codeine hypersensitivity reaction.

**Dependence**

Taking codeine regularly for a long time can lead to addiction. Stopping treatment can result in withdrawal symptoms.

Prolonged use of high doses of codeine has produced dependence of the morphine type in a very small proportion of users. Codeine produces less euphoria and sedation than morphine and is not a completely satisfactory substitute for morphine in morphine addicts.

Regular use of analgesics for headache can result in an overuse syndrome.

**Withdrawal**

Abrupt withdrawal precipitates a withdrawal syndrome. Symptoms may include tremor, insomnia, restlessness, irritability, anxiety, depression, anorexia, nausea, vomiting, diarrhoea, sweating, lacrimation, rhinorrhea, sneezing, yawning, piloerection, mydriasis, weakness, pyrexia, muscle cramps, dehydration and increase in heart rate, respiratory rate and blood pressure. These effects can also occur in neonates exposed to codeine in utero (see use in pregnancy).

Tolerance diminishes rapidly after withdrawal so a previously tolerated dose may prove fatal.

Withdrawal symptoms develop more slowly than with morphine and are milder.

**CYP2D6 Genetic polymorphism**

Codeine may be partially metabolised by CYP2D6 to morphine. Patients who are deficient in or lacking this enzyme cannot convert codeine to morphine and therefore will not obtain adequate analgesic effects. Conversely, some patients are able to convert codeine to morphine more rapidly and completely. Patients who metabolise codeine very rapidly (ultra-rapid metabolisers) are at increased risk of developing adverse effects or opioid toxicity, even at low doses. Adverse effects range from less serious symptoms such as nausea, vomiting, constipation, ‘pin-point’ pupils and dizziness or drowsiness, through to life-threatening symptoms such as shallow breathing, slow heart rate, confusion, hallucinations, seizure and coma. Healthcare professionals should inform patients about these risks and the signs and symptoms of morphine toxicity, and advise patients that if signs of toxicity are present, codeine should be stopped immediately and medical advice sought.

Estimates suggest that up to 10% of the Caucasian population may be poor metabolisers and up to 10% may be ultra-rapid metabolisers. The prevalence in Maori and Pacific people is not known.
**Use in pregnancy**

The risk-benefit balance must be carefully considered because opioid analgesics cross the placenta. Regular use during pregnancy may cause physical dependence in the foetus, leading to withdrawal symptoms (convulsions, irritability, excessive crying, tremors, hyperactive reflexes, fever, vomiting, diarrhoea, sneezing and yawning) in the neonate. Prolonged high-dose use of Codeine prior to delivery may produce Codeine withdrawal symptoms in the neonate.

Although studies for teratogenic effects in humans have not been done, studies in animals have not shown codeine to cause adverse effects on foetal development. Studies in animals have shown codeine (single dose of 100mg per kg) to cause delayed ossification in mice and (in doses of 120mg per kg) increased resorption in rats.

The administration of opioid analgesics during labour may cause respiratory depression in the newborn infant. Withdrawal symptoms in new born infants have been reported with prolonged use of this class of drug.

**Use in lactation**

Codeine is excreted into breast milk. However with usual analgesic doses, concentrations are generally low.

However, infants of nursing mothers taking codeine may have an increased risk of morphine overdose if the mother is an ultra-rapid metaboliser of codeine. When codeine enters the body and is metabolized, it changes to morphine. Nursing mothers taking codeine, who are ultra-rapid metabolisers of codeine, may have higher morphine levels in their breast milk. These higher levels of morphine in breast milk may lead to life-threatening or fatal side effects in nursing babies.

When prescribing codeine for a nursing mother, the lowest dose for the shortest amount of time to relieve pain should be prescribed. Nursing patients should be told how to recognize signs of high morphine levels in themselves and their babies.

Signs of high morphine levels in a mother are extreme sleepiness and trouble caring for the baby.

Breastfed babies usually nurse every two to three hours and should not sleep more than four hours at a time. If the baby shows signs of increased sleepiness (more than usual), difficulty breastfeeding, breathing difficulties, or limpness, the mother should immediately seek medical advice.

**Use in children**

Children may be more susceptible to the respiratory and circulatory depressant effects of opioid analgesics such as codeine. Parents and caregivers should be advised to seek medical advice immediately if signs of toxicity are present, such as excessive sleepiness, difficulty waking, difficulty breathing, confusion, slow heart rate or weak pulse. Paradoxical excitation or restlessness may also occur in paediatric patients receiving opioids.

**Use in the elderly**

Geriatric patients may be more susceptible to the effects, especially the respiratory depressant effects, of these medications. Also geriatric patients are more likely to have prostatic hypertrophy or obstruction and age-related renal function impairment, and are therefore more likely to be adversely affected by opioid-induced urinary retention. The risk of constipation and faecal impaction is also greater in the elderly.
Geriatric patients may metabolize or eliminate opioid analgesics more slowly than younger adults. Lower doses or longer dosing intervals than those usually recommended for adults may be required, and are usually therapeutically effective for these patients.

**Effects on ability to drive and operate machines**

Codeine may cause drowsiness or a decrease in alertness in some patients. Patients should be cautioned about operating vehicles or machinery, or engaging in activities which require them to be fully alert.

**ADVERSE EFFECTS**

In normal doses the commonest side effects of codeine and other opioid analgesics are nausea, vomiting, constipation (especially during chronic therapy), drowsiness and confusion. The following have been noted:

- **Immune system disorders** – rash, urticaria, pruritus, difficulty breathing, increased sweating, redness of flushed face, angioedema.
- **Nervous system disorders** – confusion, drowsiness, malaise, tiredness, vertigo, dizziness, changes in mood, hallucination, CNS excitation (restlessness/excitation), convulsions, mental depression, headache, nightmares, raised intracranial pressure, tolerance or dependence, dysphoria, hypothermia.
- **Eye disorders** – miosis, blurred or double vision.
- **Cardiac disorders** – bradycardia, palpitations, hypotension, orthostatic hypotension, tachycardia.
- **Respiratory, thoracic and mediastinal disorders** – respiratory depression.
- **Gastrointestinal Disorders** – constipation, biliary spasm, nausea, vomiting, dry mouth.
- **Musculoskeletal, connective tissue and bone disorders** – muscle rigidity.
- **Renal and urinary disorders** – ureteral spasm, anti-diuretic effect, urinary retention.
- **Reproductive system and breast disorders** – decrease in libido and potency.
- **Withdrawal effects** – abrupt withdrawal precipitates a withdrawal syndrome. Symptoms may include tremor, insomnia, restlessness, irritability, anxiety, depression, anorexia, nausea, vomiting, diarrhoea, sweating, lacrimation, rhinorrhea, sneezing, yawning, piloerection, mydriasis, weakness, pyrexia, muscle cramps, dehydration and increase in heart rate, respiratory rate and blood pressure.

Tolerance diminished rapidly after withdrawal so a previously tolerated dose may prove fatal. Regular prolonged use of codeine is known to lead to addiction and tolerance. Prolonged use of a painkiller for headaches can make them worse. These effects occur more commonly in ambient patients than in those at rest in bed. Codeine has a lower dependence liability than other opioid agonists because of its comparatively lower potency with usual doses. Withdrawal symptoms are also less severe than those produced by stronger opioid agonist analgesics.

**INTERACTIONS**

The following interactions with codeine have been noted:

- Monoamine oxidase inhibitors – due to the possible risk of excitation or depression, avoid concomitant use and for 14 days after discontinuation of MAOI
• Alcohol – enhanced sedative and hypotensive effect, increased risk of respiratory depression
• Hypnotics and anxiolytics – enhanced sedative effect, increased risk of respiratory depression
• Anticholinergics – risk of severe constipation which may lead to paralytic ileus and/or urinary retention
• Metoclopramide and domperidone – antagonistic effect on GI activity
• Anti-diarrhoeal drugs – increased risk of severe constipation
• Anaesthetics – enhanced sedative and hypotensive effect
• Tricyclic antidepressants – enhanced sedative effect
• Antipsychotics, including phenothiazines – enhanced sedative and hypotensive effect
• Opioid antagonists – may precipitate withdrawal symptoms
• Quinidine – reduced analgesic effect
• Antihypertensive drugs – enhanced hypotensive effect
• Ciprofloxacin – avoid premedication with opioids as they reduce ciprofloxacin concentration
• Ritonavir – may increase plasma levels of opioid analgesics
• Mexiletine – delayed absorption of mexiletine
• Cimetidine – inhibits the metabolism of opioid analgesics causing increased plasma codeine concentrations

OVERDOSAGE

Symptoms
Signs of overdose may include nausea, vomiting, constipation, lack of appetite, somnolence, extreme sleepiness, confusion, shallow breathing, and coma.
Signs of overdose in children include excessive sleepiness, difficulty waking, difficulty breathing, confusion, slow heart rate, weak pulse, paradoxical excitation or restlessness, and coma.
Toxic doses vary considerably with the individual and regular users may tolerate larger doses.

Treatment
The stomach should be emptied by aspiration or lavage. A laxative may be given to aid peristalsis. Intensive supportive therapy may be required to correct respiratory failure and shocks. In addition, the specific antagonist naloxone hydrochloride is used to counteract very rapidly the severe respiratory depression and coma produced by excessive doses of opioid analgesics. A dose of 0.4mg to 2mg is given intravenously, intramuscularly or subcutaneously, repeated at intervals of 2 to 3 minutes if necessary, up to 10mg. The effect of naloxone may be of shorter duration than that of the opioid analgesic and additional doses may be required to prevent relapses.
The use of opioid antagonists such as naloxone, nalorphine and levallorphan in persons physically dependent on opioid agonists may induce withdrawal symptoms.
PHARMACEUTICAL PRECAUTIONS

- Protect from light and moisture.
- Shelf life is 36 months from date of manufacture.
- Store below 25° C.
- Keep out of reach of children.

MEDICINE CLASSIFICATION

Controlled Drug C2.

PACKAGE QUANTITIES

- Codeine 15mg Tablets: 100s & 500s
- Codeine 30mg Tablets: 100s & 500s
- Codeine 60mg Tablets: 100s

FURTHER INFORMATION

Codeine is obtained from opium or made by methylating morphine. It occurs as odourless colourless crystals or white crystalline powder. The molecular formula of codeine phosphate is C_{18}H_{21}NO_{3}, H_{3}PO_{4} \cdot \frac{1}{2}H_{2}O and the molecular weight 406.4.
