1. Product Name
DAPA-TABS 2.5 mg tablets.

2. Qualitative and Quantitative Composition
Each tablet contains 2.5 mg of indapamide hemihydrate.
DAPA-TABS contain lactose. For the full list of excipients, see section 6.1.

3. Pharmaceutical Form
DAPA-TABS 2.5 mg tablets are 6.5mm, normal convex, pink, film coated tablet debossed "IE" over "2.5" on one side and "G" on the other.
Do not halve DAPA-TABS tablets.

4. Clinical Particulars

4.1 Therapeutic indications
Essential hypertension. It may be tried as a sole therapeutic agent in the treatment of mild to moderate hypertension. Normally indapamide is used as the initial agent in multiple drug regimens.

4.2 Dose and method of administration
Dose
One DAPA-TABS 2.5 mg tablet to be taken daily, by oral route, in the morning. The action of DAPA-TABS is progressive and whilst the optimum reduction in blood pressure is usually seen after four weeks, a further small but useful reduction in blood pressure may be observed over the following four to six weeks. A larger dose than one tablet (2.5 mg) of DAPA-TABS daily is not recommended as there is little additional antihypertensive effect, whilst the diuretic effect becomes more pronounced.

A single daily tablet of DAPA-TABS may effectively be combined with the following antihypertensive medicines: beta-blockers, methyldopa, clonidine, prazosin, and ACE inhibitors.

Combination with a diuretic is not recommended as significant electrolyte disturbances may occur. Indapamide has a slight but significant carry-over hypotensive effect lasting up to 1 or 2 weeks after the treatment is stopped.

Method of administration
Do not halve DAPA-TABS tablets.
4.3 **Contraindications**

- Severe renal failure, anuria, progressive and severe oliguria.
- Hepatic coma, hepatic encephalopathy or severe impairment of liver function.
- Known hypersensitivity to indapamide, other sulfonamide derivatives, or any of the excipients.
- Hypokalaemia.

4.4 **Special warnings and precautions for use**

**Electrolyte changes**

Electrolyte changes observed with indapamide become more pronounced at doses above 2.5 mg/day. The daily maximum recommended dose of DAPA-TABS is 2.5 mg administered as one tablet, since doses above 2.5 mg only increase the diuretic effect and electrolyte disturbances without any further appreciable antihypertensive effect.

**Hypokalaemia**

Hypokalaemia may occur at all doses. Symptoms of hypokalaemia include weakness, cramps, and cardiac dysrhythmias. Hypokalaemia is a particular hazard in patients treated with digoxin as dangerous or fatal arrhythmias may be precipitated. Although indapamide 2.5 mg can be safely administered to hypertensive patients with renal impairment, caution should be observed when it is administered to patients with severe renal impairment. In this case the unchanged drug is excreted primarily by the renal route, and plasma concentrations are elevated (see section 5.2).

**Uric acid**

Hyperuricaemia may occur during treatment with indapamide, and gout has been reported rarely. Tendency to gout attacks may be increased in patients with hyperuricaemia.

**Lithium**

Diuretics should not be given with lithium because they reduce its renal clearance and add a high risk of lithium toxicity (see section 4.5).

**Photosensitivity**

Cases of photosensitivity reactions have been reported with thiazides and thiazide-related diuretics. It is recommended to stop treatment if a photosensitivity reaction occurs during treatment. If re-administration of the diuretic is deemed necessary, it is recommended that areas exposed to the sun or to artificial UVA are protected.

**Lactose intolerance**

DAPA-TABS tablets contain lactose. Patients with an intolerance to lactose, rare hereditary problems of galactose intolerance, the Lapp lactase deficiency or glucose-galactose malabsorption should not take this medicine.

**Water and electrolyte balance**

Patients receiving DAPA-TABS should be monitored for signs and symptoms of fluid or electrolyte imbalance; namely hyponatraemia, hypochloraemia and hypokalaemia. Blood urea, nitrogen and uric acid should also be assessed during treatment.

The signs of electrolyte imbalance are dryness of the mouth, thirst, weakness, lethargy, drowsiness, restlessness, muscle pains or cramps, muscle fatigue, hypotension, oliguria, gastrointestinal disturbances such as nausea and vomiting, tachycardia and ECG changes.

**Plasma sodium**

This must be measured before starting treatment, then subsequently at regular intervals as treatment with any diuretic may cause hyponatraemia, sometimes with very serious consequences.
The decrease in plasma sodium may initially be asymptomatic. Regular monitoring is therefore essential and should be more frequent in the elderly and in patients with cirrhosis (see sections 4.8 and 4.9). Treatment with any diuretic may cause hyponatraemia, sometimes with very serious consequences. Hyponatraemia with hypovolaemia may be responsible for dehydration and orthostatic hypotension. Concomitant loss of chloride ions may lead to secondary compensatory metabolic alkalosis.

**Plasma potassium**

Potassium depletion with hypokalaemia is the major risk of thiazide and related diuretics. The risk of onset of hypokalaemia (<3.4 mmol/L) must be prevented in certain high risk populations, i.e. the elderly, malnourished and/or polymedicated, cirrhotic patients with oedema and ascites, and patients with coronary artery disease and/or heart failure. In these patients, hypokalaemia increases the cardiac toxicity of digitalis preparations and increases the risk of arrhythmias.

Hypokalaemia will be more common when combined with a steroid or adrenocorticotropic (ACTH) treatment and when electrolyte intake is inadequate. Individuals with a long QT interval, whether the origin is congenital or iatrogenic, are also at increased risk as hypokalaemia and bradycardia, are predisposing factors to the onset of severe arrhythmias, in particular, potentially fatal Torsades de pointes.

Plasma potassium should be measured in the first week of treatment. More frequent monitoring of plasma potassium is required in all the situations indicated above. Hypokalaemia, if detected, should be corrected.

**Plasma calcium**

Diuretic treatment should be withdrawn before the investigation of parathyroid function. Thiazide-related diuretics may decrease urinary calcium excretion and cause a slight and transitory rise in calcium. Frank hypercalcaemia may be due to previously unrecognised hyperparathyroidism.

**Severe hepatic disease**

Caution should be used when treating patients with severe hepatic disease to avoid metabolic alkalosis in cases of potassium depletion which may precipitate episodes of hepatic encephalopathy. Treatment with the diuretic must be stopped immediately if this occurs.

**Hypotension**

Orthostatic hypotension may occur and may be potentiated by alcohol, barbiturates, narcotics or concurrent therapy with other antihypertensives.

When indapamide is combined with other non diuretic antihypertensive medicines, the effects on blood pressure are additive.

**Skin reactions**

Sulfonamide derivatives have been reported to exacerbate or activate systemic lupus erythematosus. Serious allergic skin reactions (such as Stevens-Johnson syndrome) have also occasionally been reported with sulfonamides. This should be considered when using indapamide.

**Impaired renal function**

Although a DAPA-TABS dose of one 2.5 mg tablet/day can be used safely in patients with hypertension and renal impairment, treatment should be discontinued if there is an increase in azotaemia and oliguria. Studies in functionally anephric patients for one month undergoing chronic haemodialysis have not shown evidence of drug accumulation, despite the fact that indapamide is not dialysable.
A study in patients with impaired renal function demonstrated that patients with severe renal impairment (creatinine clearance 11-35 mL/min) had impaired clearance of indapamide and elevated plasma levels of the drug.

**Blood glucose**
Monitoring of blood glucose is important in patients with diabetes, in particular in the presence of hypokalaemia.

**Athletes**
DAPA-TABS contains indapamide which may give a positive reaction in doping tests.

**Use in children**
Safety and effectiveness have not been established.

**Interference with laboratory tests**
Hyperuricaemia (0.4%). Hyperglycaemia (0.4%) (see section 4.8).

The following values represent the maximum variations from pre-treatment values in occasional patients at some stage during, but not necessarily throughout treatment. Blood uric acid up 8.6%, blood glucose up 6%, BUN up 5.7%, blood creatinine up 3.6%.

**4.5 Interaction with other medicines and other forms of interaction**
No interactions have been reported between indapamide and anticoagulants, or between indapamide and uricosuric medicines.

It is recommended that indapamide not be used in combination with a diuretic since the combination may cause hypokalaemia and hyperuricaemia.

**Combinations that are not recommended**

**Lithium**
The combined use of DAPA-TABS and lithium may result in increased plasma lithium levels and produce symptoms of overdose (due to decreased urinary lithium excretion). If diuretics are necessary, careful monitoring of plasma lithium and dose adjustment are required.

**Combined use which requires special care**

**Torsades de pointes-inducing drugs**
The combined use of indapamide and Torsades de pointes-inducing drugs, including the following, is not recommended due to the increased risk of ventricular arrhythmias, particularly Torsades de pointes (hypokalaemia is a risk factor). Medicines which induce Torsades de pointes include:

- Class Ia antiarrhythmics (e.g. disopyramide)
- Class III antiarrhythmics (e.g. amiodarone, sotalol)
- Some antipsychotics: phenothiazines (e.g. trifluoperazine), benzamides (e.g. amisulpride, sulpride) and butyrophenones (e.g. droperidol, haloperidol)
- Others: diphenamid, erythromycin IV, pentamidine, moxifloxacin

Monitor (using plasma electrolytes and ECG) for hypokalaemia and correct, if required, before using DAPA-TABS and a Torsades de pointes-inducing drug in combination.

**NSAIDs (systemic route) including COX-2 selective inhibitors, high dose salicylic acid (≥ 3 g/day)**
Due to the risk of acute renal failure in patients with dehydration as a result of decreased glomerular filtration, it is recommended that hydration and renal function be monitored at the start of treatment.
Combined use with NSAIDs may also result in a reduction in the antihypertensive effect of DAPA-TABS.

**Angiotensin converting enzyme (ACE) inhibitors**

Combined use with ACE inhibitors in the presence of pre-existing sodium depletion (particularly in patients with renal artery stenosis) may increase the risk of sudden hypotension and/or acute renal failure.

In patients with hypertension when prior diuretic treatment may have caused sodium depletion, it is necessary to either:

- Stop the diuretic three days before starting treatment with the ACE inhibitor, and restart a hypokalaemic diuretic if necessary; or
- Give low initial doses of the ACE inhibitor and increase the dose gradually.

In patients with congestive heart failure, initiation with a very low dose of ACE inhibitor, possibly after a reduction in the dose of the hypokalaemic diuretic, is recommended.

The monitoring of renal function (plasma creatinine) during the first weeks of treatment with an ACE inhibitor is recommended in all patients.

**Other compounds causing hypokalaemia: amphotericin B (IV), gluco- and mineralocorticoids (systemic route), stimulant laxatives**

Due to the increased risk of hypokalaemia (additive effect).

- Monitoring, and correction if required, of plasma potassium (especially during treatment with digoxin) is recommended.
- The use of non-stimulant laxatives is recommended.

**Baclofen**

Due to the increased risk of antihypertensive effects, it is recommended that hydration and renal function be monitored at the start of treatment.

**Digoxin**

Monitoring of plasma potassium and ECG is recommended due to the increased risk of hypokalaemia following co-administration of indapamide and digoxin.

**Allopurinol**

Combined use with indapamide may increase the incidence of hypersensitivity reactions to allopurinol.

**Combinations to be taken into consideration**

**Potassium-sparing diuretics (amiloride, spironolactone, triamterene)**

Due to the increased risk of either hyperkalaemia or hypokalaemia (particularly in patients with renal failure or diabetes), care should be taken when co-administering potassium-sparing diuretics. Plasma potassium and ECG should be monitored and, if necessary, treatment reviewed.

**Metformin**

Do not co-administer with metformin when plasma creatinine exceeds 15 mg/L (135 µmol/L) in men and 12 mg/L (110 µmol/L) in women due to the increased risk of metformin induced lactic acidosis as a result of the possibility of functional renal failure associated with diuretics and more particularly with loop diuretics.

**Iodinated contrast media**
Adequate hydration before administration of the iodinated compound is recommended due to an increased risk of acute renal failure resulting from dehydration, particularly when large doses of iodinated contrast media are used.

**Imipramine-like antidepressants, neuroleptics**
Caution is recommended with these combinations due to an increased antihypertensive effect and increased risk of orthostatic hypotension.

**Calcium (salts)**
Caution is recommended with this combination due to the risk of hypercalcaemia resulting from decreased urinary elimination of calcium.

**Cyclosporin, tacrolimus**
Caution is recommended with this combination due to the risk of increased plasma creatinine without any change in circulating cyclosporin levels, even in the absence of water/sodium depletion.

**Corticosteroids (systemic route)**
Caution is recommended with this combination due to the risk of decreased antihypertensive effect (water/sodium retention due to corticosteroids).

### 4.6 Fertility, pregnancy and lactation

**Pregnancy**

**(Category C)**
Indapamide should be avoided in pregnant women and should not be used to treat oedema in pregnancy.

There are limited data with the use of indapamide in pregnant women. Prolonged exposure to thiazides during the third trimester of pregnancy can reduce maternal plasma volume as well as uteroplacental blood flow, which may cause foetal-placental ischaemia and growth retardation.

Animal studies do not indicate direct or indirect harmful effects with respect to reproductive toxicity.

Thiazides, related diuretics and loop diuretics enter the foetal circulation and may cause electrolyte disturbances. Neonatal thrombocytopenia has been reported with thiazides and related diuretics. Loop diuretics like furosemide and bumetanide are probably also associated with this risk. During the latter part of pregnancy, medicines of this type should be used with caution and at the lowest effective dose.

**Breast-feeding**
Indapamide should not be used during breast feeding. Indapamide is excreted in human breast milk and the possible effect on the newborn is unknown and cannot be excluded. Indapamide is closely related to thiazide diuretics which have been associated with a decrease in, or even suppression of, lactation. Hypersensitivity to sulfonamide-derived medicines and hypokalaemia might occur.

**Fertility**

No data available. For pre-clinical fertility data refer to section 5.3.

### 4.7 Effects on ability to drive and use machines
Indapamide does not affect vigilance but different reactions related to a decrease in blood pressure may occur in individual cases, especially at the start of treatment or when another antihypertensive
agent is added. Treatment with any blood pressure lowering agent may, therefore, affect the ability to drive, cross the road safely or operate machinery.

4.8 Undesirable effects

In general, most adverse effects are mild and transient. The most frequently reported are hypersensitivity reactions, mainly dermatological (in subjects with a predisposition to allergic and asthmatic reactions and macropapular rashes), asthenia, dizziness, headache, fatigue, muscle cramps and gastrointestinal disturbances. These usually occur within the first month of treatment. During clinical trials, hypokalaemia (plasma potassium <3.4 mmol/L) was seen in 25% of patients and < 3.2 mmol/L in 10% of patients after four to six weeks treatment. After 12 weeks treatment, the mean fall in plasma potassium was 0.41 mmol/L. Hypochloraemia 9.4%; hyponatraemia 3.1%.

The majority of adverse reactions concerning clinical or laboratory parameters are dose-dependent. Other adverse reactions have been non-specific. Cutaneous rash and impotence have been occasionally reported. Percentages shown below indicate the incidence in clinical trials.

The following undesirable effects have been observed with indapamide during treatment and are ranked according to the following frequencies: very common (≥ 1/10); common (≥ 1/100, < 1/10); uncommon (≥ 1/1,000, < 1/100); rare (≥ 1/10,000); very rare (<1/10,000); not known (cannot be estimated from the available data).

§Reported for indapamide as a post-marketing adverse effect.
‡Appropriateness of treatment with indapamide must be very carefully weighed in patients with gout or diabetes.

Other adverse reactions, reported in clinical studies with the immediate release formulation of indapamide include the following:

**Central nervous system**
Lethargy

**Gastrointestinal**
Anorexia, gastralgia, diarrhoea

**Musculoskeletal**
Joint pain, back pain, weakness of legs

**Cardiac disorders**
Tachycardia, ECG changes (non-specific ST-T changes, U waves, left ventricular strain).

**Vascular disorders**
Orthostatic hypotension

**Urogenital**
Modification of libido, polyuria

**Endocrine**
Gout

Other
Tinnitus, malaise/fainting, sweat

Laboratory abnormalities
BUN increase, blood creatinine increase

Reporting of suspected adverse reactions
Reporting suspected adverse reactions after authorisation of the medicine is important. It allows continued monitoring of the benefit/risk balance of the medicine. Healthcare professionals are asked to report any suspected adverse reactions https://nzphvc.otago.ac.nz/reporting/.

4.9 Overdose

Symptoms
Signs of acute poisoning at higher doses take the form of water/electrolyte disturbances (hyponatraemia, hypokalaemia) and may include the possibility of nausea, vomiting, hypotension, cramps, vertigo, drowsiness, confusion, polyuria or oliguria possibly to the point of anuria (by hypovolaemia). In cirrhotic patients, an overdose might precipitate hepatic coma.

Treatment
There is no specific antidote. Treatment is symptomatic and supportive. Discontinue drug; induce emesis or perform gastric lavage and/or administration of activated charcoal (activated charcoal may reduce absorption of the medicine if given within one or two hours after ingestion. In patients who are not fully conscious or have impaired gag reflex, consideration should be given to administering activated charcoal via a nasogastric tube, once the airway is protected), correct dehydration, electrolyte imbalance, hepatic coma and hypotension by established procedures.

For further advice on management of overdose please contact the National Poisons Information Centre (0800 POISON or 0800 764 766).

5. Pharmacological Properties

5.1 Pharmacodynamic properties
Pharmacotherapeutic group: Sulfonamides, plain, ATC code: C03BA11

Indapamide is a nonthiazide indole derivative of chlorosulfonamide.

Indapamide is a white crystalline lipophilic powder, soluble in methanol, ethanol, acetic acid and ethyl acetate, very slightly soluble in ether, chloroform and benzene and practically insoluble in water. Melting point is approximately 185°C.

Mechanism of action
Indapamide is an oral antihypertensive medicine. The mechanism whereby indapamide exerts its antihypertensive action has not been completely elucidated; both vascular and renal actions have been implicated.

At a dose of 2.5 mg, the renal effects of indapamide are minimal and the antihypertensive effect of indapamide has been attributed to a reduction in vascular reactivity to pressor amines. The finding that indapamide retains its antihypertensive activity in patients who are functionally anephric lends support to this hypothesis.
The renal site of action of indapamide is the proximal segment of the distal tubule. Indapamide appears to have natriuretic properties (sodium and chloride being excreted in equivalent amounts) with less effect on kaliuresis or uric acid excretion. Only at doses greater than 2.5 mg/day is an appreciable increase in urinary volume observed in man. No significant changes in plasma sodium levels have been observed in clinical studies. Significant hypokalaemia (plasma potassium <3.2 mmol/L) has been reported in some 10% of patients.

Indapamide hemihydrate 2.5 mg daily does not adversely affect serum triglycerides, LDL cholesterol, the LDL-HDL cholesterol ratio, or glucose tolerance.

5.2 Pharmacokinetic properties

Absorption
Possibly related to its high lipid solubility, absorption of indapamide from the gastrointestinal tract is rapid (within 0.5 to 1 hour after an oral dose) and complete. Bioavailability of the tablet formulation is 100% and is virtually unchanged with food or antacids.

Distribution
Indapamide is widely distributed throughout the body, with extensive binding to specific sites. In blood, it is highly bound to red blood cells (80%) and, more specifically, to carbonic acid anhydrase (98%) without significantly inhibiting activity on this enzyme.

In plasma, it is relatively highly bound to plasma proteins (79%). It is also taken up to a significant degree in the vascular compartment, the drug has a relatively low apparent volume of distribution (approximately 60 L) and 40% of the dose is located in the blood one hour after administration.

Biotransformation
Indapamide is extensively metabolised in the liver.

Elimination
After a single dose of 2.5 mg, as well as after repeated administration of 2.5 mg daily for 15 days, plasma elimination half-life of unchanged indapamide is biphasic with half-lives of 14 to 25 hours, indicating that once daily dosing is possible and that no change in kinetics occurs after repeated dosing. Steady-state plasma levels are reached within three to four days after starting treatment and the drug does not accumulate in hypertensive patients with various degrees of renal insufficiency.

Following radioactivity studies using carbon-14, the main route of elimination is the urine, but only 5 to 7% of the dose is excreted into the urine as unchanged drug; 20 to 23% of total radioactivity is eliminated into the faeces. Renal clearance of indapamide (as unchanged drug) is approximately 5 mL/minute, representing less than 10% of systemic clearance.

The high lipid solubility of the indoline moiety confers to indapamide its highly localised binding to structures in the cardiovascular system.

Linearity/non-linearity
Both single and multiple dose data indicate that indapamide’s kinetics are linear.

5.3 Preclinical safety data

Fertility
A reproductive toxicity study in rats showed no impairment of male or female fertility at oral indapamide doses up to 25 mg/kg/day, however, the number of implantation sites was reduced at the highest dose.

Carcinogenicity
Carcinogenicity studies in mice and rats showed no evidence of tumourigenicity when indapamide was administered in the diet at levels up to 100 mg/kg/day.

**Mutagenicity**

Indapamide was negative in mutagenicity tests in bacteria and bone marrow micronucleus tests in mice. There was a decrease in weight gain of the F1 generation from rats treated orally at 2.5 mg/kg/day. Galactopoiesis was affected in the F1 generation from rats treated orally at 0.5 mg/kg/day and this led to increased mortality of the F2 generation during the first 48 hours of life. No embryo-foetal toxicity or teratogenic potential were seen in rats (up to 150 mg/kg/day) and in rabbits (up to 180 mg/kg/day).

---

**6. Pharmaceutical Particulars**

**6.1 List of excipients**

DAPA-TABS also contains the following inactive ingredients: sodium starch glycollate, magnesium stearate, cellulose – microcrystalline, lactose anhydrous, croscarmellose sodium, Opadry Pink OY-6953.

DAPA-TABS are gluten free.

**6.2 Incompatibilities**

Not applicable.

**6.3 Shelf life**

3 years.

**6.4 Special precautions for storage**

Blister pack - store at or below 30°C.

Bottle – store at or below 25°C.

**6.5 Nature and contents of container**

HDPE bottle with PP cap and cotton wool rope. Pack-sizes of 30 or 100 tablets.

Blister pack. Pack sizes of 30 or 90 tablets.

Not all pack types and sizes may be marketed.

**6.6 Special precautions for disposal**

Not applicable.
