Gadovist 1.0 solution has a pH of 6.6 to 8.0

Description

Gadovist 1.0 (gadobutrol) solution for injection is the complex consisting of gadolinium (III) and the macrocyclic dihydroxy-hydroxymethylpropyl-
tetraazacyclododecane-triacetic acid (butrol), and is an injectable neutral contrast medium for magnetic resonance imaging (MRI). Gadobutrol is to be administered by intravenous injection.

Gadovist 1.0 is available as a 1.0 mmol/mL solution and each mL of Gadovist 1.0 contains 604.72 mg gadobutrol, 0.513 mg calcobutrol sodium, 1.211 mg trometamol, hydrochloric acid and water for injections. Each mL contains 0.00056 mmol (equivalent to 0.013 mg) of sodium. Based on the average amount given to a 70 kg person, this medicinal product contains less than 1 mmol sodium (23 mg) per dose.

Gadovist 1.0 injection contains no antimicrobial preservative.

**Pharmacology**

**Mechanism of action**

Gadovist 1.0 is a paramagnetic contrast agent for magnetic resonance imaging. The contrast-enhancing effect is mediated by gadobutrol, a neutral (non-ionic) complex consisting of gadolinium (III) and the macrocyclic ligand dihydroxy-hydroxymethylpropyl-tetraazacyclododecane-triacetic acid (butrol).

In T₂*-weighted gradient echo sequence the induction of local magnetic field inhomogeneties by the large magnetic moment of gadolinium and at high concentrations (during bolus injection) leads to a signal decrease of tissues in such sequences.

**Pharmacodynamic effects**

Gadobutrol leads to distinct shortening of the relaxation times even in low concentrations. At pH 7 and 40°C the relaxivity (r₁) [determined from the influence on the spin-lattice relaxation time (T₁) of protons in plasma] is about 5.6 L/mmol-sec and the relaxivity (r₂) [determined from the influence on the spin-spin relaxation time (T₂)] is about 6.5 L/mmol-sec. The relaxivity displays only slight dependency on the strength of the magnetic field.

The macrocyclic ligand forms a firm complex with the paramagnetic gadolinium ion with extremely high *in-vivo* and *in-vitro* stability. Gadobutrol is a highly water-soluble, extremely hydrophilic compound with a distribution coefficient between n-butanol and buffer at pH 7.6 of about 0.006. The substance does not display any particular protein binding or inhibitory interaction with enzymes.

**Pharmacokinetics**

After intravenous administration, gadobutrol is rapidly distributed in the extracellular space and is eliminated in an unchanged form via the kidneys by glomerular filtration. The extrarenal elimination is negligible.
The pharmacokinetics of gadobutrol in humans were dose proportional (e.g. \( C_{\text{max}} \), AUC). After doses up to 0.4 mmol gadobutrol/kg body weight, the plasma level declined after an early distribution phase with a half-life of about 90 minutes, identical to the renal elimination rate. After a dose of 0.1 mmol gadobutrol/kg body weight, 0.59 mmol gadobutrol/L plasma was measured 2 minutes after the injection and 0.3 mmol gadobutrol/L plasma 60 minutes post-injection. Within two hours more than 50 % of the given dose was eliminated via the urine. After a dose of 0.1 mmol gadobutrol/kg body weight about 100.3 ± 2.6 % of the dose was excreted within 72 h after administration. Less than 0.1 % was eliminated via the faeces. The average renal clearance of gadobutrol was found to be about 120 mL/min and was, therefore, comparable to that of other highly hydrophilic (water-soluble) biologically inert substances like inulin. No metabolites were detected in plasma or urine.

**Renal Impairment**

In patients with impaired renal function, the serum half-life of gadobutrol is prolonged and correlated with the reduction in creatinine clearance.

The mean terminal half-life was prolonged to 5.8 hours in moderately impaired patients (80>CL\(_{\text{CR}}\)\(>30 \) mL/min) and further prolonged to 17.6 hours in severely impaired patients not on dialysis (CL\(_{\text{CR}}\)<30 mL/min).

The mean serum clearance was reduced to 0.49 mL/min/kg in mild to moderately impaired patients (80>CL\(_{\text{CR}}\)>30 mL/min) and to 0.16 mL/min/kg in severely impaired patients not on dialysis (CL\(_{\text{CR}}\)<30 mL/min).

Complete recovery in the urine was seen in patients with mild or moderate renal impairment within 72 hours. In patients with severely impaired renal function about 80 % of the administered dose was recovered in the urine within 5 days (also see Precautions and Dosage and Administration).

Gadobutrol is cleared by haemodialysis with approximately 70% of a given dose eliminated during the first haemodialysis session and 98% eliminated after the third session, regardless of the dose given.

**Elderly population**

Due to physiological changes in renal function with age, in healthy elderly volunteers (aged 65 years and above), systemic exposure was increased by approximately 33% (men) and 54% (women) and terminal half-life was increased by approximately 33% (men) and 58% (women). The plasma clearance is reduced by approximately 25% (men) and 35% (women), respectively. The recovery of the administered dose in urine was complete after 24 hours in all volunteers and there was no difference between elderly and non-elderly healthy volunteers.

**Investigation in animals**

In rats it has been demonstrated that gadobutrol does not penetrate the intact blood-brain barrier.
In rabbits, the placental transfer was insignificant, 0.01 % of the administered dose being detected in the foetuses.

In lactating rats, less than 0.1% of the total administered dose was excreted into the breast milk.

In rats, absorption after oral administration was found to be very small and amounted to about 5 % based on the fraction of the dose excreted in urine.

Enterohepatic circulation has not been observed.

**Clinical Trials**

**Contrast-Enhanced Magnetic Resonance Imaging (CE–MRI) of the whole body including head and neck region, thoracic space, breast, abdomen, pelvis, retroperitoneal space, extremities and musculoskeletal system and cardiac MRI**

The use of Gadovist 1.0 in CE-MRI of the whole body is supported by company-sponsored studies and a systematic review of the literature.

**CE-MRI of the liver and kidneys**

Results from three clinical studies involving 1,234 patients (2 pivotal and one open-label study), demonstrated non-inferiority of Gadovist 1.0 compared to Magnevist (dimeglumine gadopentetate), for diagnosing malignant lesions in liver and kidneys in CE–MRI at a dose of 0.1 mmol/kg BW. The primary efficacy variables were accuracy and increase in diagnostic accuracy from pre- to combined pre- and post-contrast MRI scans. Efficacy was measured from clinical studies and blinded readings. Other assessments from the 2 pivotal studies to support the comparable efficacy of Gadovist 1.0 to Magnevist in CE–MRI were lesion extent, lesion sub-classification, technical efficacy and therapeautic impact. The standard of reference for each study was assessment by an independent Truth Panel or against a predefined and independent Standard of Truth, (SOT).

Results from the two pivotal studies are summarised in the table below:
**Table 2: Results from pivotal studies in CE-MRI of the liver and kidneys**

Aim: Demonstrate Non-Inferiority of Gadovist 1.0 to Magnevist in CE-MRI of body (liver and kidneys) compared to a pre-defined Standard of Truth.

Non-inferiority (equivalence) limit (Δ) set at 95% Confidence Interval of >-0.1 (10%) for accuracy and >-0.04 (4%) for increase in diagnostic accuracy

**Result:** Performance of Gadovist 1.0 is comparable to Magnevist for both studies

**CE-MRI of the breast**

Patients with recently diagnosed breast cancer were enrolled in two clinical trials designed to evaluate the efficacy of Gadovist 1.0 for the assessment of malignant breast disease prior to surgery. Patients underwent pre-contrast breast MRI prior to administration of Gadovist 1.0 at a dose of 0.1 mmol/kg, followed by post-contrast breast MRI. For both studies, pre-contrast (UMRM) and pre-plus-post contrast breast images (CMRM) were independently evaluated by three readers for the presence or absence of malignancy. The standard of truth (SoT) consisted of histopathologically confirmed malignant disease or alternatively X-ray mammography (XRM) plus ultrasound for non-malignant disease.
For each study, the co-primary endpoints were the demonstration of superior sensitivity for the detection of malignancy on a subject level of CMRM image sets compared to UMRM image sets and demonstration of the correct exclusion of malignancy (specificity) based on disease free breasts of greater than 80% by CMRM for the same 2 of 3 independent readers.

The two identical clinical trials, GEMMA-1 and GEMMA-2, evaluated a total of 787 subjects. Efficacy results presented for GEMMA-1 are based upon post-hoc analyses of the original clinical data. In GEMMA-1, 390 subjects were assessed, all were female and the average age was 55.7 years. For GEMMA-2, 397 subjects were assessed, 396 were female, 1 was male and the average age was 57.1 years.

In both trials, Gadovist 1.0-enhanced breast MRI demonstrated superior detection of malignancy compared to unenhanced MRI. The addition of XRM to the CMRM did not substantially improve the detection of malignancy by CMRM (Table 3).

As all subjects had a confirmed malignancy, specificity was calculated on a breast level. Most subjects had a malignancy in one breast and no disease in the other (contralateral) breast. The specificity of Gadovist 1.0-enhanced breast MRI, based on breasts with no malignancy, was greater than the performance threshold of 80% for all blinded readers in GEMMA-1 and for 2 of 3 blinded readers in GEMMA-2 (Table 4).

a Three additional independent readers evaluated XRM alone for each study

For both studies, the co-primary endpoints were met simultaneously for two of the three readers for sensitivity and specificity.

**CE-MRI of the body**

A multi-centre, randomised, single-blind, parallel-group comparison, Phase III study (13297), investigated the efficacy and safety of Gadovist 1.0 compared to Magnevist following a single injection in Asian patients referred for contrast-enhanced MRI of the body (including breast, heart, abdomen, kidney, pelvis, or extremities). One hundred and seventy-eight (178) patients received Gadovist 1.0 and 185 patients received Magnevist.

The primary objective was to demonstrate non-inferiority of unenhanced plus Gadovist 1.0-enhanced MRI compared to unenhanced plus Magnevist-enhanced MRI at a dose of 0.1 mmol/kg body weight based on the evaluation of three primary efficacy variables: contrast enhancement, border delineation and internal morphology of lesions, which in combination were linked to the detection and visualisation of lesions in the body regions.

The total scores (mean ± SD) of these three visualisation parameters for combined (unenhanced plus enhanced) images were 9.39 ± 1.06 for Gadovist 1.0, and 9.34 ± 1.23 for Magnevist in the per protocol set (PPS) population (Table 5). Statistical analysis demonstrated that Gadovist 1.0 was non-inferior to Magnevist in lesion visualisation.

a) Gadovist 1.0 minus Magnevist
Abbreviation: n, number of subjects

Contrast-Enhanced Magnetic Resonance Angiography, (CE-MRA)

Two pivotal studies including 362 patients have been performed in which the diagnostic efficacy of Gadovist 1.0-enhanced MRA with that of intra-arterial Digital Subtraction Angiography (i.a. DSA) was compared clinically and by blinded reader re-evaluation. In one study, the aorta and supra-aortal, thoracic, and abdominal branch vessels (1 FOV), and in the other study pelvic and peripheral arteries (3 FOVs), were evaluated. The following table summarises the dose information and the agreement rates between Gadovist 1.0 mmol/mL enhanced MRA and i.a. DSA regarding differentiation between non-relevantly and relevantly diseased vessel segments.
Table 7: Results from pivotal studies in CE-MRA

Lower agreement rates have been observed predominantly in vessel segments with small diameter such as vertebral arteries and arteries of the calf due to limited spatial resolution. The coronary arteries have not been included in any study and contrast-enhanced MRA with Gadovist 1.0 mmol/mL can thus not be recommended for this indication.

Use in Children less than 18 years

Two single pharmacokinetic (PK) Phase I/III studies in paediatric populations have been performed to investigate PK, safety and efficacy at the standard intravenous dose of 0.1 mmol/kg body weight. The first study (310788) was conducted in 138 children between 2 to 17 years of age. The second study (91741) was conducted in 44 children from birth to less than 2 years of age (including full-term newborns). Efficacy and safety were assessed as secondary endpoints.

Results of the studies demonstrated that body weight was the main covariate that affects clearance and volume of distribution. The PK profile of gadobutrol in children of all ages is similar to that in adults, resulting in similar values for area under the curve (AUC), body weight normalised plasma clearance (CL) and volume of distribution (Vss), as well as elimination half-life and excretion rate.

Approximately 99% (median) of the dose was recovered in urine within 6 hours (this information was derived from the 2 to <18 year old age group).

Diagnostic efficacy and an increase in diagnostic confidence was demonstrated for all parameters evaluated in the studies and there was no difference among the paediatric age groups and when compared to adults.

A summary of post hoc estimated and derived PK parameters for children and adults is presented in the tables below.
Table 8: Simulated Gd plasma concentrations at 20 min and 30 min after application of 0.1 mmol/kg body weight (BW) in adults, paediatric subjects 2 – 17 years and paediatric subjects 0 - < 2 years

**Indications**

This medicinal product is for diagnostic use only.

Gadovist 1.0 is indicated in adults and children of all ages including full-term newborns\(^*\) for:

**Contrast enhancement in cranial and spinal magnetic resonance imaging (MRI).**

For spinal MRI this includes: Differentiation of intra- and extramedullary tumours, demonstration of solid tumour areas in known syrinx, determination of intramedullary tumour spread.
Gadovist 1.0 is especially suited for high dose indications, such as cases where the exclusion or demonstration of additional foci may influence the therapy or patient management, for detection of very small lesions and for visualisation of lesions that do not readily take up contrast media.

Gadovist 1.0 is also indicated for perfusion studies such as the diagnosis of stroke, the detection of focal cerebral ischaemia and tumour perfusion.

Contrast enhancement in whole body MRI including head and neck region, thoracic space, breast, abdomen (pancreas, liver and spleen), pelvis (prostate, bladder and uterus), retroperitoneal space (kidney), extremities and musculoskeletal system.#

Contrast enhancement in magnetic resonance angiography (CE MRA).

Contrast enhancement in cardiac MRI including assessment of rest and pharmacological stress perfusion and delayed enhancement.#

Contraindications

Gadovist 1.0 should not be administered to patients with known hypersensitivity to any of the ingredients.

Precautions

WARNING NEPHROGENIC SYSTEMIC FIBROSIS

Gadolinium-based contrast agents increase the risk of nephrogenic systemic fibrosis (NSF) in patients with:

- Acute or chronic severe renal insufficiency (glomerular filtration rate <30 mL/min/1.73m²), or
- Acute renal insufficiency of any severity due to the hepato-renal syndrome or in the perioperative liver transplantation period,

See Contraindications and Precautions.

General

Pronounced states of excitement, anxiety and pain may increase the risk of adverse reactions or intensify contrast medium related reactions.
Hypersensitivity

As with other intravenous contrast agents, Gadovist 1.0 can be associated with anaphylactoid/hypersensitivity or other idiosyncratic reactions, characterised by cardiovascular, respiratory or cutaneous manifestations, and ranging to severe reactions including shock.

The risk of hypersensitivity reactions is higher in case of:

- Previous reaction to contrast media
- History of bronchial asthma
- History of allergic disorders

In patients with an allergic disposition the decision to use Gadovist 1.0 must be made after particularly careful evaluation of the risk-benefit ratio.

Most of these reactions occur within half an hour of administration. Therefore, post-procedure observation of the patient is recommended.

Medications for the treatment of hypersensitivity reactions as well as preparedness for institution of emergency measures are necessary.

Delayed reactions (after hours and up to several days) have rarely been observed (see Adverse Effects).

Patients taking beta blockers who experience such reactions may be resistant to treatment with beta agonists.

Severe Renal Impairment and Liver Transplant Patients

No impairment of renal function has so far been observed with the administration of Gadovist 1.0.

Prior to administration of Gadovist 1.0 all patients should be screened for renal dysfunction by obtaining a history and/or laboratory tests.

In patients with severely impaired renal function the benefits must be weighed carefully against the risks, since contrast medium elimination is delayed in such cases.

Because gadobutrol is renally excreted sufficient period of time for elimination of the contrast agent from the body prior to any re-administration in patients with renal impairment should be ensured. Usually, complete recovery in the urine was seen in patients with mild or moderate renal impairment within 72 hours. In patients with severely impaired renal function at least 80% of the administered dose was recovered in the urine within 5 days (see also Clinical Pharmacology, Pharmacokinetics).
There have been reports of nephrogenic systemic fibrosis (NSF) associated with the use of gadolinium-containing contrast agents including Gadovist 1.0 in patients with:

- acute or chronic severe renal impairment (a glomerular filtration rate < 30 mL/min/1.73m²) or
- acute renal insufficiency of any severity due to the hepato-renal syndrome or in the peri-operative liver transplantation period.

NSF is a debilitating and sometimes fatal disease affecting the skin, muscle, and internal organs.

Therefore, Gadovist 1.0 should only be used in these patients after careful risk/benefit assessment.

When administering a gadolinium-based contrast agent (GBCA), do not exceed the dose recommended in the product labelling. Allow sufficient time for elimination of the GBCA prior to any re-administration.

Gadovist 1.0 can be removed from the body by haemodialysis. After three dialysis sessions approximately 98% of the agent is removed from the body.

For patients already receiving haemodialysis at the time of Gadovist 1.0 administration, prompt initiation of haemodialysis following the administration of Gadovist 1.0 should be considered, in order to enhance the contrast agent’s elimination.

**Severe Cardiovascular Disease**

In patients with severe cardiovascular disease Gadovist 1.0 should only be administered after careful risk-benefit assessment because so far only limited data are available.

**Seizure Disorders**

As with other gadolinium-chelate-containing contrast media, special precaution is necessary in patients with a low threshold for seizures.

**Cerebral Perfusion Studies**

Information to support the clinical usefulness of MRI studies of cerebral perfusion is limited. Clinical studies were conducted only in patients with a unilateral carotid artery stenosis and/or unilateral cerebral infarct who were assessed as being in a clinically stable condition.

**Non-clinical Safety Data**

Non-clinical data reveal no special hazard for humans based on conventional studies of systemic toxicity, genotoxicity, and contact-sensitizing potential.
Experimental local tolerance studies following single and repeated intravenous administration and single intraarterial administration in animals did not result in adverse local effects.

Experimental local tolerance studies in animals following single paravenous, subcutaneous and intramuscular applications, indicated that slight local intolerance reactions could occur at the administration site after inadvertent paravenous administration.

In non-clinical cardiovascular safety pharmacology studies, depending on the dose of gadobutrol administered, transient increases in blood pressure and myocardial contractility were observed. As these effects were minimal and transient, and due to anaesthesia of the animals, they are not considered relevant to humans. An increase in blood pressure was not observed in human clinical studies.

**Genotoxicity, Carcinogenicity and Impairment of Fertility**

Bacteria, mammalian cells and animal studies investigating the genotoxicity (gene mutation and chromosomal aberration) of gadobutrol *in-vitro* and *in-vivo* did not show a genotoxic potential.

The carcinogenic potential of gadobutrol has not been investigated in long-term animal studies.

A repeat-dose study of reproduction toxicity in rats resulting in systemic exposures (plasma AUC) exceeding the human exposure at the maximum recommended dose by a factor of about 5 did not indicate any impairment of fertility.

**Use in Pregnancy – Category B3**

For gadobutrol no clinical study data on exposed pregnancies are available.

Gadobutrol was not teratogenic in rats, rabbits or monkeys even when given repeatedly during organogenesis at maximum dose levels tested being 8 to 32 times (based on body surface area) or 25 to 100 times (based on body weight) above the diagnostic dose in humans.

In reproductive toxicology studies repeated intravenous dosing of gadobutrol caused retardation of the embryonal development in rats and rabbits and an increase in embryo-lethality in rats, rabbits and monkeys at dose levels being 8 to 16 times (based on body surface area) or 25 to 50 times (based on body weight) above the diagnostic dose in humans. It is not known whether these effects can also be induced by a single administration.

The potential risk for humans is unknown.

Gadovist 1.0 should not be used during pregnancy unless clearly necessary.
Use in Lactation

It is unknown whether gadobutrol is excreted in human milk.

There is evidence from a study in rats that gadobutrol is excreted into breast milk in very small amounts (less than 0.1% of the dose intravenously administered) and absorption via the gastrointestinal tract is poor (about 5% of the dose orally administered to adult rats was excreted in the urine).

$^{153}$Gd-labelled gadobutrol was administered intravenously to lactating rats at a dose of 0.5 mmol/kg. About 3 hours after dosing, 0.01% of the total dose was transferred into milk. Twenty-four hours after dosing radioactivity was still detectable in milk found in the stomach of the fetuses. In the blood of suckling neonates, the labelled gadobutrol was detected at about 1% of the maternal blood level 3 hours after dosing. In a peri- and postnatal study, F1 female offspring of rats dosed at 4.5 mmol/kg/day showed a slight delay in the development of CNS function in the conditioned avoidance reaction test.

At clinical doses, no effects on the infant are anticipated and Gadovist 1.0 can be used during breastfeeding.

Studies in neonatal/juvenile animals

Single and repeat-dose toxicity studies in neonatal and juvenile rats did not reveal findings suggestive of a specific risk for use in children of all ages including full-term newborns and infants.

Interactions with Other Medicines

No interactions studies with other medicines have been conducted.

Effects on ability to drive or use machines

Not known

Adverse Effects

Summary of the safety profile

The overall safety profile of gadobutrol is based on data from more than 6,300 patients in clinical trials, and from post-marketing surveillance.

The most frequently observed adverse drug reactions ($\geq 0.5\%$) in patients receiving gadobutrol are headache, nausea and dizziness.

The most serious adverse drug reactions in patients receiving gadobutrol are cardiac arrest and severe anaphylactoid reactions.

Delayed allergoid reactions (hours later up to several days) have been rarely observed.
Most of the undesirable effects were of mild to moderate intensity.

**Tabulated list of adverse reactions**

The adverse drug reactions observed with gadobutrol are represented in the table below. They are classified according to System Organ Class (MedDRA version 14.1). The most appropriate MedDRA term is used to describe a certain reaction and its synonyms and related conditions.

Adverse drug reactions from clinical trials are classified according to their frequencies. Frequency groupings are defined according to the following convention: common: ≥ 1/100 to < 1/10; uncommon: ≥ 1/1,000 to < 1/100; rare: ≥ 1/10,000 to < 1/1,000. The adverse drug reactions identified only during post-marketing surveillance, and for which a frequency could not be estimated, are listed under ‘not known’.

Within each frequency grouping, undesirable effects are presented in order of decreasing seriousness.

**Table 10: Adverse drug reactions (ADR) reported in clinical trials or during post-marketing surveillance in patients treated with gadobutrol**

* There have been reports of life-threatening and/or fatal outcomes from this ADR.

∞ None of the individual symptoms ADRs listed under hypersensitivity/anaphylactoid reaction identified in clinical trials reached a frequency greater than rare (except for urticaria)

§ Hypersensitivity / anaphylactoid reactions identified only during post-marketing surveillance (frequency not known)

0 Injection site reactions (various kinds) comprise the following terms: Injection site extravasation, injection site burning, injection site coldness, injection site warmth, injection site erythema or rash, injection site pain, injection site haematoma

**Additional information on special populations**

**Paediatric patients**

Based on two single dose Phase I/III studies in 138 subjects aged 2-17 years and 44 subjects aged 0-<2 years, the frequency, type and severity of adverse drug reactions in children of all ages including full-term newborns are consistent with the adverse drug reaction profile known in adults. This has been confirmed in a Phase IV study including more than 1,100 paediatric patients and postmarketing surveillance.
Dosage and Administration

General Information

The dose required is administered intravenously as a bolus injection. Contrast-enhanced MRI can commence immediately afterwards (shortly after the injection depending on the pulse sequences used and the protocol for the examination). Optimal signal enhancement is observed during arterial first pass for CE-MRA and within a period of about 15 minutes after injection of Gadovist 1.0 for other indications (time depending on type of lesion/tissue).

Gadovist 1.0 should not be drawn into the syringe, and the prefilled syringe should not be prepared, until immediately before use. Gadovist 1.0 is for use in a single patient only. Any contrast medium solution not used in one examination must be discarded.

T₁-weighted scanning sequences are particularly suitable for contrast-enhanced examinations.

The usual safety rules for magnetic resonance imaging must be observed, e.g. exclusion of cardiac pacemakers and ferromagnetic implants.

Intravenous administration of contrast media should, if possible, be done with the patient lying down. After the administration, the patient should be kept under observation for at least 30 minutes, since experience with contrast media shows that the majority of all undesirable effects occur within this time.

Nausea and vomiting are known adverse reactions associated with administration of all extracellular MRI contrast media. The patient should therefore refrain from eating for two hours prior to investigation in order to minimise risk of vomiting and possible aspiration.

Dosage

Adults

Dosage depends on indication. A single intravenous injection of 0.1 mL Gadovist 1.0/kg body weight is recommended for most indications. A total amount of 0.3 mL Gadovist 1.0/kg body weight may be administered at maximum.

Cranial and Spinal MRI

0.1 mmol/kg body weight (equivalent to 0.1 mL Gadovist 1.0 mmol/kg body weight), given intravenously at a rate of 2 mL per second.

In some investigations use of further doses of 0.1 mmol/kg (equivalent to 0.1 mL/kg Gadovist 1.0) or 0.2 mmol/kg body weight (equivalent to 0.2 mL/kg Gadovist 1.0), to a total of 0.3 mmol/kg body weight (equivalent to 0.3 mL/kg Gadovist 1.0) may yield additional information.
CE MRI of the whole body#

0.1 mL/kg body weight of the 1.0 mmol/mL Gadovist 1.0 solution (equivalent to 0.1 mmol/kg body weight) is recommended.

Cerebral Perfusion Studies (see Precautions)

For gradient echo sequences 0.1 - 0.3 mmol/kg body weight (equivalent to 0.1 - 0.3 mL/kg) Gadovist 1.0 given intravenously at a rate of 5 mL per second using a powered injector is recommended.

Contrast–enhanced magnetic resonance angiography, CE MRA

*Imaging of one field of view:*

7.5 mL for body weight below 75 kg

10 mL for body weight of 75 kg and higher

(corresponding to 0.1 - 0.15 mmol/kg body weight)

*Imaging more than one field of view:*

15 mL for body weight below 75 kg

20 mL for body weight of 75 kg and higher

(corresponding to 0.2 - 0.3 mmol/kg body weight)

CE Myocardial Perfusion Imaging and Delayed Enhancement#

The recommended dose is 0.05 mL/kg body weight during pharmacological stress and 0.05 mL/kg body weight at rest of the 1.0 mmol/mL Gadovist 1.0 solution (equivalent to a total dose of 0.1 mL/kg body weight or 0.1 mmol/kg body weight).

For delayed enhancement only, a total dose of 0.1 mL/kg body weight is also recommended.

Paediatric patients

For children of all ages including full-term newborns, the recommended dose is 0.1 mmol Gadovist 1.0 per kg body weight (equivalent to 0.1 mL Gadovist 1.0 per kg body weight) for all indications, see Indication(s).

Due to immature renal function in newborns and infants up to 1 year of age, Gadovist 1.0 should only be used in these patients after careful consideration at a dose not exceeding 0.1 mmol/kg body weight. More than one dose should not be used during a scan. Because of the lack of information on repeated administration, Gadovist 1.0 injections should not be repeated unless the interval between injections is at least 7 days.
**Elderly patients**

In clinical studies, no overall differences in safety or effectiveness were observed between elderly (aged 65 years and above) and younger patients, and other reported clinical experience has not identified differences in responses between the elderly and younger patients. No dosage adjustment is considered necessary.

**Patients with renal impairment**

Do not exceed the recommended dose (see Pharmacokinetics, Renal Impairment; Precautions [boxed warning] and Precautions, Severe Renal Impairment and Liver Transplant Patients).

---

**Overdosage**

No signs of intoxication secondary to an overdose have so far been reported during clinical use. Single doses of gadobutrol as high as 1.5 mmol/kg body weight were well tolerated. In case of inadvertent overdosage, cardiovascular monitoring (including ECG) and control of renal function are recommended as a measure of precaution.

Gadovist 1.0 can be removed from the body by haemodialysis (see Precautions).

In cases of overdose, it is advisable to contact the Poisons Information Centre for recommendations on the management and treatment of overdosage.

---

**Presentation and Storage Conditions**

Gadovist 1.0 M is a solution containing 604.72 mg/mL gadobutrol. Gadovist 1.0 is supplied in 15 mL glass vials, 5 mL and 7.5 mL (in 10 mL) glass prefilled syringes and 5 mL, 7.5 mL (in 10 mL), 10 mL, 15 mL and 20 mL plastic prefilled syringes. Not all presentations may be marketed.

Gadovist 1.0 should be stored below 30°C.

After the vial has been opened or the prefilled syringe has been prepared for use, Gadovist 1.0 remains stable for 24 hours at 20 to 25°C and must be discarded thereafter.

**Incompatibilities**

In the absence of compatibility studies, this medicinal product must not be mixed with other medicinal products.
Instructions for Use/Handling

Visual inspection

This medicinal product should be visually inspected before use. Gadovist 1.0 should not be used in case of severe discoloration, the occurrence of particulate matter or a defective container.

Vials

Gadovist 1.0 should only be drawn into the syringe immediately before use. The rubber stopper should never be pierced more than once. Any contrast medium solution not used in one examination must be discarded.

Prefilled syringes

The prefilled syringe must be taken from the pack and prepared for the injection immediately before the administration.

The tip cap should be removed from the prefilled syringe immediately before use. Any contrast medium solution not used in one examination must be discarded.
