1 COMPOSITION

Each capsule contains Ibuprofen 400 mg and the following excipient(s):
Polyethylene Glycol 600, Potassium hydroxide, Miglyol 812N (Medium chain triglyceride), OPACODE WB monogramming ink NS-78-17821 Black, Gelatin 160 Bloom, Sorbitol Liquid Partially Dehydrated (Polysorb 85/70/00).

2 PHARMACEUTICAL FORM

Capsule, soft

Natural transparent, oval shaped, soft gelatin capsule containing clear colourless liquid. imprinted with L 160 in Black edible ink.

3 CLINICAL PARTICULARS

3.1 Therapeutic indications

This medical product is indicated in adults and children & adolescents 12 years of age and over for the symptomatic treatment of mild to moderate pain and/or inflammation associated with headache, migraine, tension headache, muscular pain, dental pain, period pain, sinus pain, back pain, arthritis pain, cold and flu symptoms.

3.2 Dosage and administration

For oral use and short-term use only. Capsules should not be chewed.

Undesirable effects may be minimized by using the lowest effective dose for the shortest possible duration necessary to control symptoms (see section 3.4)

Adults and children & adolescents 12 years of age and over. Initial dose, one capsule with water. Then, if necessary, one capsule every six hours. Do not exceed six capsules (2400 mg) in any 24-hour period.

If in children and adolescents between 12 and 18 years this medicinal product is required for 3 days, or if symptoms worsen a doctor should be consulted.
If in adults the product is required for more than 3 days in the case of fever and 4
days for treatment of pain, or if the symptoms worsen the patient is advised to
consult a doctor.

It is recommended that patients with a sensitive stomach take Ibuprofen with food.

If taken shortly after eating, the onset of action of Ibuprofen may be delayed. If this
happens do not take more Ibuprofen than recommended within section 3.2
(posology) or until the correct re-dosing interval has passed.

**Special patient groups**

**Elderly:**

No special dose adjustment is required. Because of the possible undesirable-effect
profile (see section 3.4), the elderly should be monitored particularly carefully.

**Renal insufficiency:**

No dose reduction is required in patients with mild to moderate impairment to
renal function (patients with severe renal insufficiency, see section 3.3).

**Hepatic insufficiency (see section 4.2):**

No dose reduction is required in patients with mild to moderate impairment to
hepatic function (patients with severe hepatic dysfunction, see section 3.3).

**Children and adolescents:**

For use in children and adolescents, see section 3.3.

### 3.3 Contraindications

- Hypersensitivity to the active substance or to any of the other excipients listed in
  section 5.1.

- In patients with a history of hypersensitivity reactions (e.g. bronchospasm, asthma,
  rhinitis, angioedema or urticaria) associated with the intake of acetylsalicylic acid
  (ASA) or other non-steroidal anti-inflammatory drugs (NSAIDs).

- History of gastrointestinal bleeding or perforation, related to previous NSAIDs
  therapy.

- Active, or history of recurrent peptic ulcer/haemorrhage (two or more distinct
  episodes of proven ulceration or bleeding).

- Patients with severe hepatic failure, severe renal failure, or severe heart failure
  (NYHA Class IV). See also section 3.4.
• In patients with cerebrovascular or other active bleeding.

• In patients with bleeding diathesis or coagulation disorders.

• In patients with unclarified blood-formation disturbances.

• In patients with severe dehydration (caused by vomiting, diarrhoea or insufficient fluid intake).

• During the last trimester of pregnancy (see Section 3.6).

• Adolescents weighing less than 40 kg or children under 12 years of age.

3.4 Special warnings and precautions for use

Undesirable effects may be minimised by using the lowest effective dose for the shortest possible duration necessary to control symptoms (see gastrointestinal (GI) and cardiovascular risks below).

Caution is required in patients with certain conditions, which may be made worse:

• systemic lupus erythematosus and mixed connective tissue disease – increased risk of aseptic meningitis (see section 3.8).

• congenital disorder of porphyrin metabolism (e.g. acute intermittent porphyria).

• gastrointestinal disorders and chronic inflammatory intestinal disease (ulcerative colitis, Crohn’s disease) (see section 3.8).

• hypertension and/or cardiac impairment (see section 3.3 and 3.8).

• renal impairment as renal function may deteriorate (see sections 3.3 and 3.8).

• hepatic dysfunction (see sections 3.3 and 3.8).

• directly after major surgery.

• in patients who show allergic reactions to other substances, as they are also at a higher risk of hypersensitivity reactions when using Ibuprofen.

• in patients who suffer from hayfever, nasal poyps, chronic obstructive respiratory disorders, or have a history of allergic disease, as an increased risk exists for them of allergic reactions occurring. These may present as asthma attacks (so-called analgesics asthma). Quincke’s oedema or urticaria.

Gastrointestinal (GI) safety
The use with concomitant NSAID’s, including cyclo-oxygenase-2 specific inhibitors, increases risk of adverse reactions (see section 3.5) and should be avoided.

Elderly:
The elderly have an increased frequency of adverse reactions to NSAIDs especially
gastrointestinal (GI) bleeding and perforation which may be fatal (see section 3.2).

**Gastrointestinal (GI) bleeding, ulceration or perforation:**

Gastrointestinal (GI) bleeding, ulceration or perforation, which can be fatal has been reported with all NSAIDs at any time during treatment, with or without warning symptoms or a previous history of GI events.

When GI bleeding or ulceration occurs in patients receiving ibuprofen, the treatment should be withdrawn.

The risk of GI bleeding, ulceration or perforation is higher with increasing NSAID doses and patients with a history of ulcer, particularly if complicated with haemorrhage or perforation (see section 3.3) and in the elderly. These patients should commence treatment on the lowest dose available. Combination therapy with protective agents (e.g. misoprostol or proton pump inhibitors) should be considered for these patients, and also for patients requiring concomitant low dose acetylsalicylic acid, or other drugs likely to increase gastrointestinal risk (see below and section 3.5).

Patients with a history of GI toxicity, particularly the elderly, should report any unusual abdominal symptoms (especially GI bleeding) particularly in the initial stages of treatment.

Caution should be advised in patients receiving concomitant medications which could increase the risk of ulceration or bleeding, such as oral corticosteroids, anticoagulants such as warfarin, selective serotonin-reuptake inhibitors (SSRI’s) or anti-platelet agents such as aspirin (see section 3.5).

NSAID’s should be given with care to patients with a history of gastrointestinal disease (ulcerative colitis, Crohn’s disease) as these conditions may be exacerbated (see section 3.8).

**Skin reactions**

Serious skin reactions, some of them fatal, including exfoliative dermatitis, Stevens-Johnson syndrome and toxic epidermal necrolysis, have been reported very rarely in association with the use of NSAIDs (see section 3.8). Patients appear to be at highest risk of these reactions early in the course of therapy: the onset of the reaction occurring in the majority of cases within the first month of treatment. Ibuprofen should be discontinued at the first appearance of skin rash, mucosal lesions, or any other sign of hypersensitivity.

Exceptionally, varicella can be at the origin of serious cutaneous and soft tissues infectious complications. To date, the contributing role of NSAIDs in the worsening of these infections cannot be ruled out. Thus, it is advisable to avoid use of Nurofen in case of varicella.

**Cardiovascular and cerebrovascular effects**

Caution (discussion with doctor or pharmacist) is required prior to starting treatment in patients with a history of hypertension and/or heart failure as fluid retention, hypertension and oedema have been reported in association with NSAID therapy.

Clinical studies suggest that the use of ibuprofen, particularly at high doses (2400 mg daily) may be associated with a small increased risk of arterial thrombotic events (for example myocardial infarction or stroke). Overall, epidemiological studies do not suggest that low dose ibuprofen (e.g. \( \leq 1200 \) mg daily) is associated with an increased risk of arterial thrombotic events.
Patients with uncontrolled hypertension, congestive heart failure (NYHA II-III),
established ischaemic heart disease, peripheral arterial disease, and/or cerebrovascular
disease should only be treated with ibuprofen after careful consideration and high
doses (2400 mg/day) should be avoided.

Careful consideration should also be exercised before initiating long-term treatment
for patients with risk factors for cardiovascular events (e.g. hypertension,
hyperlipidaemia, diabetes mellitus, smoking), particularly if high doses of ibuprofen
(2400 mg/day) are required.

Other notes
Severe acute hypersensitivity reactions (for example anaphylactic shock) are
observed very rarely. At the first signs of a hypersensitivity reaction after
taking/administering Ibuprofen therapy must be stopped. Medically required
measures, in line with the symptoms, must be initiated by specialist personnel.

Ibuprofen, the active substance of Ibuprofen Liquid Capsules may temporarily inhibit
the blood-platelet function (thrombocyte aggregation). Therefore, it is recommended
to monitor patients with coagulation disturbances carefully.

In prolonged administration of Ibuprofen regular checking of the liver values, the
kidney function, as well as of the blood count, is required.

Prolonged use of any type of painkiller for headaches can make them worse. If this
situation is experienced or suspected, medical advice should be obtained and
treatment should be discontinued. The diagnosis of medication overuse headache
(MOH) should be suspected in patients who have frequent or daily headaches despite
(or because of) the regular use of headache medications.

The habitual intake of painkillers, particularly the combination of several painkillers,
may lead to permanent renal damage with the risk of renal failure (analgesic
nephropathy). This risk may be increased by salt loss and dehydration.

Through concomitant consumption of alcohol, active substance-related undesirable
effects, particularly those that concern the gastrointestinal tract or the central nervous
system, may be increased on use of NSAID’s.

There is some evidence that drugs which inhibit cyclo-oxygenase/prostaglandin
synthesis may cause impairment of female fertility by an effect on ovulation. This is
reversible on withdrawal of treatment (see section 3.6).

There is a risk of renal impairment in dehydrated adolescents.

The medicinal product contains sorbitol. Patients with rare hereditary problems of
fructose intolerance should not take this medicine.

3.5 Interaction with other medicinal products and other forms of interaction

Acetylsalicylic acid (low dose):
Concomitant administration of ibuprofen and acetylsalicylic acid is not generally
recommended because of the potential of increased adverse effects.

Experimental data suggest that ibuprofen may competitively inhibit the effect of low dose acetylsalicylic acid on platelet aggregation when they are dosed concomitantly. Although there are uncertainties regarding extrapolation of these data to the clinical situation, the possibility that regular, long-term use of ibuprofen may reduce the cardioprotective effect of low-dose acetylsalicylic acid cannot be excluded. No clinical relevant effect is considered to be likely for occasional ibuprofen use (see section 4.1).

Other NSAIDs, including cyclooxygenase-2 selective inhibitors:

The concomitant administration of several NSAIDs may increase the risk of gastrointestinal ulcers and bleeding due to a synergistic effect. The concomitant use of ibuprofen with other NSAIDs should therefore be avoided (see section 3.4).

Digoxin, phenytoin, lithium:

The concomitant use of Ibuprofen with digoxin, phenytoin or lithium preparations may increase serum levels of these medicinal products. A check of serum-lithium, serum-digoxin and serum-phenytoin levels is not as a rule required on correct use (maximum over 4 days).

Corticosteroids:

Corticosteroids as these may increase the risk of adverse reactions, especially of the gastrointestinal tract (gastrointestinal ulceration or bleeding) (see Section 3.3).

Anti-platelet agents and selective serotonin reuptake inhibitors (SSRIs):

Increased risk of gastrointestinal bleeding. (See section 3.4).

Anticoagulants:

NSAIDs may enhance the effect of anti-coagulants, such as warfarin (see section 3.4).

Probenecid and sulfinpyrazone:

Medicinal products that contain probenecid or sulfinpyrazone may delay the excretion of ibuprofen.

Diuretics, ACE inhibitors, betareceptor-blocker and angiotensin-II antagonists:

NSAIDs may reduce the effect of diuretics and other antihypertensive drugs. In some patients with compromised renal function (e.g. dehydrated patients or elderly patients with compromised renal function) the co-administration of an ACE inhibitor, betareceptor-blocker or angiotensin-II antagonist and agents that inhibit cyclooxygenase may result in further deterioration of renal function, including possible acute renal failure, which is usually reversible. Therefore, the combination should be administered with caution, especially in the elderly. Patients should be adequately hydrated and consideration should be given to monitoring of renal function after
initiation of concomitant therapy, and periodically thereafter.

**Potassium sparing diuretics:**
The concomitant administration of Ibuprofen and potassium-sparing diuretics may lead to hyperkalaemia (check of serum potassium is recommended).

**Methotrexate:**
The administration of Ibuprofen within 24 hours before or after administration of methotrexate may lead to elevated concentrations of methotrexate and an increase in its toxic effect.

**Ciclosporin:**
The risk of a kidney-damaging effect due to ciclosporin is increased through the concomitant administration of certain nonsteroidal antiinflammatory drugs. This effect also cannot be ruled out for a combination of ciclosporin with ibuprofen.

**Tacrolimus:**
The risk of nephrotoxicity is increased if the two medicinal products are administered concomitantly.

**Zidovudine:**
There is evidence of an increased risk of haemarthroses and haematoma in HIV (+) haemophiliacs receiving concurrent treatment with zidovudine and ibuprofen. Increased risk of haematological toxicity when NSAIDs are given with zidovudine.

**Sulfonylureas:**
Clinical investigations have shown interactions between nonsteroidal anti-inflammatory drugs and antidiabetics (sulphonylureas). Although interactions between ibuprofen and sulphonylureas have not been described to date, a check of blood-glucose values is recommended as a precaution on concomitant intake.

**Quinolone antibiotics:**
Animal data indicate that NSAID’s can increase the risk of convulsions associated with quinolone antibiotics. Patients taking NSAID’s and quinolones may have an increased risk of developing convulsions.

**Mifepristone:**
NSAIDs should not be used for 8-12 days after mifepristone administration as NSAIDs can reduce the effect of mifepristone.
3.6 **Fertility, Pregnancy and lactation**

**Pregnancy:**
Inhibition of prostaglandin synthesis may adversely affect the pregnancy and/or the embryo/foetal development. Data from epidemiological studies raise concern about an increased risk of miscarriage and of cardiac malformation and gastroschisis after use of a prostaglandin synthesis inhibitor in early pregnancy. The absolute risk for cardiovascular malformation was increased from less than 1%, up to approximately 1.5%. The risk is believed to increase with dose and duration of therapy.

In animals, administration of a prostaglandin synthesis inhibitor has been shown to result in increased pre- and post-implantation loss and embryo-foetal lethality. In addition, increased incidences of various malformations, including cardiovascular, have been reported in animals given a prostaglandin synthesis inhibitor during the organogenetic period.

During the first and second trimester of pregnancy, ibuprofen should not be given unless clearly necessary. If ibuprofen is used by a woman attempting to conceive, or during the first and second trimester of pregnancy, the dose should be kept as low and duration of treatment as short as possible.

During the third trimester of pregnancy, all prostaglandin synthesis inhibitors may expose
- the foetus to:
  - cardiopulmonary toxicity (with premature closure of the ductus arteriosus and pulmonary hypertension);
  - renal dysfunction, which may progress to renal failure with oligo-hydroamniosis;
- the mother and the neonate, at the end of pregnancy, to:
  - possible prolongation of bleeding time, an anti-aggregating effect which may occur even at very low doses;
  - inhibition of uterine contractions resulting in delayed or prolonged labour.

Consequently, ibuprofen is contraindicated during the third trimester of pregnancy.

**Lactation:**
Ibuprofen and its metabolites can pass in low concentrations into the breast milk. No harmful effects to infants are known to date, so for short-term treatment with the recommended dose for pain and fever interruption of breast-feeding would generally not be necessary.

**Fertility:**
The use of ibuprofen may affect female fertility. This effect is reversible on withdrawal of treatment. Therefore use of ibuprofen is not recommended in women having difficulties becoming pregnant (see section 3.4.).

3.7 **Effects on ability to drive and use machines**

Patients who experience dizziness, drowsiness, vertigo or visual disturbances while they are taking ibuprofen, should avoid driving or using machinery. Single
administration or short term use of ibuprofen does not usually warrant the adoption of any special precautions. This applies to a greater extent in combination with alcohol.

**3.8 Undesirable effects**

The list of the following undesirable effects comprises all undesirable effects that have become known under treatment with ibuprofen, also those under high-dose long-term therapy in rheumatism patients. The stated frequencies, which extend beyond very rare reports, refer to the short-term use of daily doses up to a maximum of 1200 mg ibuprofen for oral dosage forms and a maximum of 1800 mg for suppositories.

With the following adverse drug reactions, it must be accounted for that they are predominantly dose-dependent and vary interindividually.

The most commonly observed adverse events are gastrointestinal in nature. Peptic ulcers, perforation or GI bleeding, sometimes fatal, particularly in the elderly may occur (see section 4.4). Nausea, vomiting, diarrhoea, flatulence, constipation, dyspepsia, abdominal pain, melaena, haematemesis, ulcerative stomatitis, exacerbation of colitis and Crohn's disease (see section 3.4) have been reported following administration. Less frequently, gastritis has been observed. Particularly the risk of gastrointestinal bleeding occurring is dependent on the dose range and the duration of use.

Oedema, hypertension and cardiac failure have been reported in association with NSAID treatment.

Clinical studies suggest that use of ibuprofen, particularly at a high dose (2400 mg/day) may be associated with a small increased risk of arterial thrombotic events (for example myocardial infarction or stroke) (see section 3.4).

Hypersensitivity reactions have been reported and these may consist of:

(a) non-specific allergic reactions and anaphylaxis
(b) respiratory tract reactivity, eg asthma, aggravated asthma, bronchospasm, dyspnoea
(c) various skin reactions, e.g. pruritus, urticaria, angioedema and more rarely exfoliative and bullous dermatoses (including epidermal necrolysis and erythema multiforme)

The patient is to be instructed to inform a doctor at once and to stop taking ibuprofen if they experience any of the above.
Please note that within each frequency grouping, undesirable effects are presented in order of decreasing seriousness.

**Infections and infestations:**

Very rare: Exacerbation of infection-related inflammations (e.g. development of necrotising fasciitis) coinciding with the use of nonsteroidal anti-inflammatory drugs has been described. This is possibly associated with the mechanism of action of the nonsteroidal anti-inflammatory drugs.

If signs of an infection occur or get worse during use of Ibuprofen, the patient is therefore recommended to go to a doctor without delay. It is to be investigated whether there is an indication for an anti-infective/antibiotic therapy.

The symptoms of aseptic meningitis with neck stiffness, headache, nausea, vomiting, fever or consciousness clouding have been observed under ibuprofen. Patients with autoimmune disorders (SLE, mixed connective-tissue disease) appear to be predisposed.

**Blood and Lymphatic System Disorders:**

Very rare: Disturbances to blood formation (anaemia, leukopenia, thrombocytopenia, pancytopenia, agranulocytosis). The first signs may be fever, sore throat, superficial wounds in the mouth, influenza-like complaints, severe lassitude, nosebleeds and skin bleeding. In such cases the patient should be advised to discontinue the medicine immediately, to avoid any self-medication with analgesics or antipyretics and to consult a physician.

The blood count should be checked regularly in long-term therapy.

**Immune system disorders (Hypersensitivity):**

Uncommon: Hypersensitivity reactions with urticaria and pruritus, as well as asthma attacks (possibly with drop in blood pressure).

Very rare: severe general hypersensitivity reactions. Symptoms could be: facial, tongue and laryngeal swelling, dyspnoea, tachycardia, hypotension, (anaphylaxis,
angioedema or severe shock).
Exacerbation of asthma and bronchospasm.

Psychiatric disorders:
Very rare: Psychotic reactions, depression

Nervous System Disorders:
Uncommon: Central nervous disturbances such as headache, dizziness, sleeplessness, agitation, irritability or tiredness

Eye disorders:
Uncommon: Visual disturbances

Ear and Labyrinth disorders:
Rare: Tinnitus

Cardiac Disorders:
Very rare: palpitations, heart failure, myocardial infarction

Vascular disorders:
Very rare: Arterial hypertension

Gastrointestinal Disorders:
Common: Gastro-intestinal complaints such as dyspepsia, pyrosis, abdominal pain, nausea, vomiting, flatulence, diarrhoea, constipation and slight gastro-intestinal blood losses that may cause anaemia in exceptional cases

Uncommon: Gastrointestinal ulcers, potentially with bleeding and perforation. Ulcerative stomatitis, exacerbation of colitis and Crohn's disease (see section 3.4), gastritis

Very rare: Oesophagitis, pancreatitis, formation of intestinal diaphragm-like strictures.

The patient is to be instructed to withdraw the medicinal product and to go to a doctor immediately if severe pain in the upper abdomen or melaena or haematemesis occurs.

Hepatobiliary Disorders:
Very rare: Hepatic dysfunction, hepatic damage, particularly in long-term therapy, hepatic failure, acute hepatitis
Skin and Subcutaneous Tissue Disorders:
Very rare: Bullous reactions including Stevens-Johnson syndrome and toxic epidermal necrolysis, alopecia. In exceptional cases, severe skin infections and soft-tissue complications may occur during a varicella infection (see also "Infections and infestations").

Renal and Urinary Disorders:
Rare: Kidney-tissue damage (papillary necrosis) and elevated uric acid concentrations in the blood may also occur rarely

Very rare: Formation of oedemas, particularly in patients with arterial hypertension or renal insufficiency, nephrotic syndrome, interstitial nephritis that may be accompanied by acute renal insufficiency. Renal function should therefore be checked regularly.

3.9 Overdose

In adolescents and adults the dose response effect is not clear cut. The half-life in overdose is 1.5-3 hours

Symptoms
Most patients who have ingested clinically important amounts of NSAIDs will develop no more than nausea, vomiting, epigastric pain, or more rarely diarrhoea. Tinnitus, headache and gastrointestinal bleeding are also possible. In more serious poisoning, toxicity is seen in the central nervous system, manifesting as dizziness, drowsiness, occasionally excitation and disorientation or coma. Occasionally patients develop convulsions. In serious poisoning metabolic acidosis may occur and the prothrombin time/ INR may be prolonged, probably due to interference with the actions of circulating clotting factors. Acute renal failure and liver damage may occur. Exacerbation of asthma is possible in asthmatics.

Management
Management should be symptomatic and supportive and include the maintenance of a clear airway and monitoring of cardiac and vital signs until stable. Consider oral administration of activated charcoal if the patient presents within 1 hour of ingestion of a potentially toxic amount. If frequent or prolonged, convulsions should be treated with intravenous diazepam or lorazepam. Give bronchodilators for asthma.

4 PHARMACOLOGICAL PROPERTIES

4.1 Pharmacodynamic properties

Pharmacotherapeutic group: Anti-inflammatory and antirheumatic products, non-
Ibuprofen is a nonsteroidal anti-inflammatory drug (NSAID) that in the conventional animal-experiment inflammation models has proven to be effective via prostaglandin-synthesis inhibition. In humans, ibuprofen reduces inflammatory-related pain, swellings and fever. Furthermore, ibuprofen reversibly inhibits ADP – and collagen – induced platelet aggregation.

Experimental data suggests that ibuprofen may competitively inhibit the effect of low dose acetylsalicylic acid on platelet aggregation when they are dosed concomitantly. Some pharmacodynamics studies show that when single doses of ibuprofen 400mg were taken within 8 h before or within 30 min after immediate release acetylsalicylic acid dosing (81 mg), a decreased effect of acetylsalicylic acid on the formation of thromboxane of platelet aggregation occurred. Although there are uncertainties regarding extrapolation of these data to the clinical situation, the possibility that regular, long-term use of ibuprofen may reduce the cardioprotective effect of low-dose acetylsalicylic acid cannot be excluded. No clinically relevant effect is considered to be likely for occasional ibuprofen use (see section 3.5).

4.2 Pharmacokinetic properties

On oral administration, ibuprofen is partly absorbed in the stomach and then completely in the small intestine.

Following hepatic metabolism (hydroxylation, carboxylation, conjugation), the pharmacologically inactive metabolites are completely eliminated, mainly renally (90 %), but also with the bile. The elimination half-life in healthy individuals and those with liver and kidney diseases is 1.8 - 3.5 hours. Plasma-protein binding is about 99 %.

Peak plasma levels following oral administration of a normal-release pharmaceutical form (tablet) are reached after 1 - 2 hours. Ibuprofen is absorbed rapidly from the gastrointestinal tract following oral administration. In a pharmacokinetic study (R07-1009), the time to peak plasma levels (median Tmax) in fasted state, for normal-release pharmaceutical form ibuprofen acid tablets was 90 min compared with 40 min for Ibuprofen Capsules, soft. Ibuprofen is detected in the plasma for more than 8 hours after administration of Ibuprofen.

4.3 Preclinical safety data

The subchronic and chronic toxicity of ibuprofen in animal experiments was observed principally as lesions and ulcerations in the gastro-intestinal tract. *In vitro* and *in vivo* studies gave no clinically relevant evidence of a mutagenic potential of ibuprofen. In studies in rats and mice no evidence of carcinogenic effects of ibuprofen was found. Ibuprofen led to inhibition of ovulation in rabbits as well as disturbance of implantation in various animal species (rabbit, rat, mouse). Experimental studies have
demonstrated that ibuprofen crosses the placenta, for maternally toxic doses, an increased incidence of malformations (e.g. ventricular septal defects) was observed. In animal studies it has been observed that the use of NSAIDs, known to inhibit prostaglandin synthesis, may increase the incidence of dystocia and delayed parturition.

5 PHARMACEUTICAL PARTICULARS

5.1 List of excipients

Fill
Polyethylene glycol-600
Potassium hydroxide
Purified water

Miscellaneous:
Polyethylene Glycol 600
Miglyol 812N

Gelatin Mass:
Gelatin 160 Bloom
Sorbitol Liquid, Partially dehydrated (polysorb 85/70/00)

Ink:
OPACODE WB Black NS-78-17821

5.2 Incompatibilities

Not applicable.

5.3 Shelf life

2 years

5.4 Special precautions for storage

Do not store above 30°C. Store in the original package to protect from moisture and light

5.5 Nature and contents of container

Blister, white opaque PVC/PE/ PVDC aluminium. Each blister tray contains 6, 10, 12, 20, 24, 30, 40, 48 or 50 capsules, soft. The blisters are packed in a cardboard carton. Not all pack sizes may be marketed.
5.6 Special precautions for disposal

No special requirements.
