Data Sheet

Name of Medicine

IMIPENEM+CILASTATIN RBX

*imipenem/cilastatin*
500 mg /500 mg powder for solution for infusion

Presentation

IMIPENEM+CILASTATIN RBX for intravenous use is supplied as a white to pale yellow sterile powder in 30 mL vials. Each vial contains 500 mg of imipenem equivalent and 500 mg cilastatin equivalent. The reconstituted solution is clear (however variations in colour from colourless to yellow do not affect the potency of the product).

Note: IMIPENEM+CILASTATIN RBX for intramuscular use is not available in New Zealand.

Therapeutic Class

Cilastatin is a competitive, reversible and specific inhibitor of dehydropeptidase-I enzyme.

Imipenem is a beta-lactam antibacterial agent.

Indications

The activity of IMIPENEM+CILASTATIN RBX against an unusually broad spectrum of pathogens makes it particularly useful in the treatment of polymicrobial mixed aerobic/anaerobic infections as well as initial therapy prior to the identification of the causative organisms. IMIPENEM+CILASTATIN RBX is indicated for the treatment of the following infections due to susceptible organisms:

- Intra-abdominal infections
- Lower respiratory tract infections
- Gynaecological infections
- Septicaemia
- Genitourinary tract infections
- Bone and joint infections
- Skin and soft tissue infections
- Endocarditis

IMIPENEM+CILASTATIN RBX is indicated for the treatment of mixed infections caused by susceptible strains of aerobic and anaerobic bacteria. The majority of these mixed infections are associated with contamination by faecal flora or flora originating from the vagina, skin and mouth. In these mixed infections, *Bacteroides fragilis* is the most commonly encountered anaerobic pathogen and is usually resistant to aminoglycosides, cephalosporins and penicillins. However, *Bacteroides fragilis* is usually
susceptible to imipenem and cilastatin combination. Imipenem and cilastatin combination has demonstrated efficacy against many infections caused by aerobic and anaerobic gram-positive and gram-negative bacteria resistant to the cephalosporins, including cefazolin, cefoperazone, cephalothin, cefoxitin, cefotaxime, moxalactam, cefamandole, ceftazidime and ceftriaxone. Similarly, many infections caused by organisms resistant to aminoglycosides (gentamicin, amikacin, tobramycin) and/or penicillins (ampicillin, carbenicillin, penicillin-G, ticarcillin, piperacillin, azlocillin, mezlocillin) responded to treatment imipenem and cilastatin. IMIPENEM+CILASTATIN RBX is not indicated for the treatment of meningitis.

**Dosage and Administration**

The dosage recommendations for IMIPENEM+CILASTATIN RBX (for intravenous use only) represent the quantity of imipenem to be administered. An equivalent amount of cilastatin is also present. The total daily dosage of IMIPENEM+CILASTATIN RBX should be based on the type or severity of infection and given in equally divided doses based on consideration of degree of susceptibility of the pathogens, renal function and body-weight.

*Adult Dosage Schedule for Patients with Normal Renal Function*

Doses cited in Table 1 are based on a patient with normal renal function (creatinine clearance of > 70 mL/min/1.73m²) and a body weight of ≥ 70 kg. A reduction in dose must be made for a patient with a creatinine clearance ≤ 70 mL/min/1.73m² (see Table 2) and/or a body weight < 70 kg. The reduction for body weight is especially important for patients with much lower body weights and/or moderate/severe renal insufficiency. Most infections respond to a daily dose of 1-2 g administered in 3-4 divided doses. For the treatment of moderate infection, a 1 g b.i.d. dosage regimen may also be used. In infections due to less susceptible organisms, the daily dosage of IMIPENEM+CILASTATIN RBX may be increased to a maximum of 4 g/day or 50 mg/kg/day, whichever is lower. Each dose of ≤ 500 mg of IMIPENEM+CILASTATIN RBX should be given by intravenous infusion over 20 to 30 minutes. Each dose > 500 mg should be infused over 40 to 60 minutes. In patients who develop nausea during the infusion, the rate of infusion may be slowed.

*A further proportionate reduction in dose administered must be made for patients with a body weight < 70 kg.*

Due to high antimicrobial activity of IMIPENEM+CILASTATIN RBX, it is recommended that the maximum total daily dosage not exceed 50 mg/kg/day of 4 g/day, whichever is lower. However cystic fibrosis patients with normal renal function have been treated with IMIPENEM+CILASTATIN RBX at doses up to 90 mg/kg/day in divided doses not exceeding 4 g/day.

IMIPENEM+CILASTATIN RBX has been used successfully as monotherapy in immunocompromised cancer patients for confirmed or suspected infections such as sepsis.

**Adult Dosage Schedule for Patients with Impaired Renal Function**

To determine the reduced dose for adults with impaired renal function:

1. The total daily dose is chosen from Table 1 based on infection characteristics.
2. From Table 2 the appropriate reduced dosage regimen is selected based on the daily dose from Table 1 and the patient’s creatinine clearance category. (For infusion times see Adult Dosage Schedule for Patients with Normal Renal Function).
* A further proportionate reduction in dose administered must be made for patients with a body weight < 70 kg.

When the 500 mg dose is used in patients with creatinine clearances of 6 - 20 mL/min/1.73 m² there may be an increased risk of seizures. Patients with creatinine clearances of \(\leq 5\) mL/min/1.73 m² should not receive IMIPENEM+CILASTATIN RBX I.V. unless haemodialysis is instituted within 48 hours.

**Haemodialysis**

When treating patients with creatinine clearances of \(\leq 5\) mL/min/1.73 m² who are undergoing haemodialysis, use the dosage recommendations for patients with creatinine clearances of 6 - 20 mL/min/1.73 m² (see Adult Dosage Schedule for Patients with Impaired Renal Function). Both imipenem and cilastatin are cleared from the circulation during haemodialysis. The patient should receive IMIPENEM+CILASTATIN RBX after haemodialysis and at 12 hour intervals timed from the end of that haemodialysis session. Dialysis patients, especially those with background CNS disease, should be carefully monitored; for patients on haemodialysis, IMIPENEM+CILASTATIN RBX is recommended only when the benefit outweighs the potential risk of seizures (see Warnings and Precautions). Currently there are inadequate data to recommend use of IMIPENEM+CILASTATIN RBX for patients on peritoneal dialysis.

Renal status of elderly patients may not be accurately portrayed by measurement of BUN or creatinine alone. Determination of creatinine clearance is suggested to provide guidance for dosing in such patients.

**Paediatric Dosing Schedule (3 months or older)**

For children and infants the following dosage schedule is recommended:

a. CHILDREN \(\geq 40\) kg body weight should receive adult doses.

b. CHILDREN AND INFANTS <40 kg body weight should receive 15 mg/kg at six-hour intervals. The total daily dose should not exceed 2 g.

Clinical data are insufficient to recommend dosing for children less than 3 months of age, or paediatric patients with impaired renal function (serum creatinine >2 mg/dL).

IMIPENEM+CILASTATIN RBX is not recommended for the therapy of meningitis. If meningitis is suspected, an appropriate antibiotic should be used.

IMIPENEM+CILASTATIN RBX may be used in children with sepsis as long as they are not suspected of having meningitis.

**Reconstitution, Intravenous Solution**

IMIPENEM+CILASTATIN RBX for intravenous infusion is supplied as a white sterile powder in vials containing 500 mg imipenem equivalent and 500 mg cilastatin equivalent.
IMIPENEM+CILASTATIN RBX is buffered with sodium bicarbonate to provide solutions in the pH range of 6.5 to 8.5. There is no significant change in pH when solutions are prepared and used as directed.

IMIPENEM+CILASTATIN RBX contains 37.5 mg of sodium (1.6 mEq).

Sterile powder IMIPENEM+CILASTATIN RBX should be reconstituted as shown in Table 3. 0.9% sodium chloride is the recommended diluent.

Preparation of Imipenem+Cilastatin 30 mL vial

The vials are single use only.

1. Check before use that there is no foreign material in the powder and that the seal between the cap and the vial is intact.
2. Remove the cap by twisting and pulling until the seal breaks.
3. Add approximately 10 mL from the appropriate infusion solution to the vial. Shake well.
4. Transfer the resulting suspension to the infusion solution container. Caution: The suspension is not for direct infusion.
5. Repeat steps 3 and 4 until the vial is completely empty.
6. The resulting mixture in the infusion container should be shaken until the mixture becomes clear.
7. The reconstituted solution should be inspected visually for particulate matter and discoloration prior to administration. Do not use until the reconstituted solution is clear. The colour may vary from colourless to yellow without affecting potency.
8. After reconstitution: The product should be used immediately. Any unused solution and the vial should be adequately disposed of.

Stability, IMIPENEM+CILASTATIN RBX

Store below 25°C.

CAUTION: IMIPENEM+CILASTATIN RBX is chemically incompatible with lactate and should not be reconstituted in diluents containing lactate.
IMIPENEM+CILASTATIN RBX can be administered, however, into an I.V. system through which a lactate solution is being infused.

IMIPENEM+CILASTATIN RBX should not be mixed with or physically added to other antibiotics.

**Contraindications**
Hypersensitivity to any component of this product.

**Warnings and Precautions**

**General**
There is some clinical and laboratory evidence of partial cross-allergenicity between imipenem and cilastatin combination and the other beta-lactam antibiotics, penicillins and cephalosporins. Severe reactions (including anaphylaxis) have been reported with most beta-lactam antibiotics. Before therapy with IMIPENEM+CILASTATIN RBX, careful inquiry should be made concerning previous hypersensitivity reactions to beta-lactam antibiotics. If an allergic reaction to IMIPENEM+CILASTATIN RBX occurs, the medicine should be discontinued and appropriate measures undertaken. The concomitant use of IMIPENEM+CILASTATIN RBX and sodium valproate is not recommended (see Interactions). Pseudomembranous colitis has been reported with virtually all antibiotics and can range from mild to life-threatening in severity. Antibiotics should, therefore, be prescribed with caution in individuals with a history of gastrointestinal disease, particularly colitis. It is important to consider a diagnosis of pseudomembranous colitis in patients who develop diarrhoea in association with antibiotic use. While studies indicate that a toxin produced by *Clostridium difficile* is a primary cause of antibiotic-associated colitis, other causes should also be considered.

**Use in Pregnancy**
There are no adequate and well controlled studies in pregnant women. IMIPENEM+CILASTATIN RBX should be used during pregnancy only if the potential benefit justifies the potential risk to the foetus.

**Nursing Mothers**
Imipenem has been detected in human milk. If the use of IMIPENEM+CILASTATIN RBX is deemed essential, the patient should stop nursing.

**Paediatric Use**
Clinical data are insufficient to recommend the use of imipenem and cilastatin for children under 3 months of age or paediatric patients with impaired renal function (serum creatinine >2 mg/dL). (See also Paediatric Dosage Schedule.)

**Central Nervous System**
As with other beta lactam antibiotics, CNS side effects such as myoclonic activity, confusional states, or seizures have been reported, especially when
recommended dosages based on renal function and bodyweight were exceeded. These experiences have been reported most commonly in patients with CNS disorders (e.g. brain lesions or history of seizures) and/or compromised renal function in whom accumulation of the administered entities could occur. Hence, close adherence to recommended dosage schedules is urged, especially in these patients (see Dosage and Administration). Anticonvulsant therapy should be continued in patients with a known seizure disorder. If focal tremors, myoclonus, or seizures occur, patients should be elevated neurologically and placed on anticonvulsant therapy if not already instituted. If CNS symptoms continue, the dosage of IMIPENEM+CILASTATIN RBX should be decreased or discontinued. Patients with creatinine clearances of $\leq 5$ mL/min/1.73 m$^2$ should not receive IMIPENEM+CILASTATIN RBX unless haemodialysis is instituted within 48 hours. For patients on haemodialysis, IMIPENEM+CILASTATIN RBX is recommended only when the benefit outweighs the potential risk of seizures.

**Animal Toxicity**

Animal studies showed that the toxicity produced by imipenem, as a single entity, was limited to the kidney. Nephrotoxicity (characterised by proximal tubular necrosis) was observed in rabbits and monkeys receiving high doses of imipenem. The rabbit is more sensitive to the nephrotoxic effect of imipenem than the monkey. No adverse effects were observed after six months of imipenem administration in rats, at dosage levels up to 180 mg/kg/day, or in monkeys given up to 120 mg/kg/day. No adverse effects were noted after intravenous administration of cilastatin to rats and monkeys at dosages up to 500 mg/kg/day for 14 weeks and five weeks, respectively. Acute studies with cilastatin supported the conclusion that this medicine is relatively non-toxic. In rats given 1250 mg/kg/day subcutaneously, or larger doses, very slight to slight proximal renal tubular degeneration was observed. After 5 weeks on these doses, no tubular necrosis was found, and there were no changes in any other tissues. Renal function remained normal. Co-administration of cilastatin with imipenem in a 1:1 ratio prevented the nephrotoxic effects of imipenem in rabbits and monkeys, even when the dose of imipenem was 360 mg/kg/day or 180 mg/kg/day, respectively (dosage levels which are nephrotoxic when administered without cilastatin). This protective effect was seen in the monkey throughout six months of co-administration. Rabbits receiving 14C-imipenem, at a dose known to cause proximal tubular degeneration, showed accumulation in their renal cortex of two radiolabelled metabolites of imipenem, accounting for 8 percent of the administered doses. A majority of radioactivity was found as hydrolysed imipenem, the product of DHP-I mediated metabolism. A second metabolite accumulating in the kidney, but undetectable in either plasma or urine, has been identified as a cysteine-adduct of imipenem, generated by a pathway independent of DHP-I. Levels of free imipenem in the cortex were much lower than those of either of the two metabolites. Co-administration of a protective dose of cilastatin results in a major reduction in levels of accumulated hydrolysed imipenem but not of the cysteine-adduct. Neither of the two metabolites caused renal damage, when administered intravenously to the rabbit at high dose rates.
Available evidence suggests that cilastatin prevents the nephrotoxicity of imipenem in animals, by preventing entry of imipenem into the tubular cells.

The intravenous LD50 of imipenem is greater than 2000 mg/kg in the rat and approximately 1500 mg/kg in the mouse.

The intravenous LD50 of cilastatin sodium is approximately 5000 mg/kg in the rat and approximately 8700 mg/kg in the mouse.

The intravenous LD50 of imipenem and cilastatin is approximately 1000 mg/kg in the rat and approximately 1100 mg/kg in the mouse.

Genotoxicity studies were performed in a variety of bacterial and mammalian tests *in vivo* and *in vitro*. The tests were: V79 mammalian cell mutation assay (imipenem, imipenem-cilastatin), Ames test (cilastatin, imipenem), unscheduled DNA synthesis assay (imipenem-cilastatin) and *in vivo* mouse cytogenicity test (imipenem-cilastatin). None of these tests showed any evidence of genetic damage.

Reproduction tests in male and female rats were performed with imipenem and cilastatin combination in doses up to 320 mg/kg/day. Slight decreases in live foetal body-weight were observed at this high dosage level. No other adverse effects were observed in fertility, reproductive performance, foetal viability, growth or post-natal development of pups. Similarly, no adverse effects on the foetus or on lactation were observed when imipenem-cilastatin was administered to rats late in gestation.

Teratogenicity studies with cilastatin sodium in rabbits and rats at 10 and 33 times the usual human dose of imipenem and cilastatin (30 mg/kg/day) respectively, showed no evidence of adverse effect on the foetus. No evidence of teratogenicity or adverse effect on postnatal growth or behaviour was observed in rats given imipenem at dosage levels up to 30 times the usual human intravenous dose. Similarly, no evidence of adverse effect on the foetus was observed in teratology studies in rabbits with imipenem at 2 times the usual human intravenous dose.

Teratology studies with imipenem-cilastatin sodium at doses up to 11 times the usual human intravenous dose in pregnant mice and rats, during the period of major organogenesis, revealed no evidence of teratogenicity.

Imipenem-cilastatin sodium, when administered to pregnant rabbits at dosages equivalent to the usual human dose of the intravenous formulation and higher, caused body weight loss, diarrhoea, and maternal deaths. When comparable doses of imipenem-cilastatin sodium were given to non-pregnant rabbits, body weight loss, diarrhoea, and deaths were also observed. This intolerance is not unlike that seen with other beta-lactam antibiotics in this species and is probably due to alteration of gut flora.
A teratology study in pregnant cynomolgus monkeys given imipenem-cilastatin sodium at doses of 40 mg/kg/day (bolus intravenous injection) or 160 mg/kg/day (subcutaneous injection) resulted in maternal toxicity including emesis, inappetence, body weight loss, diarrhoea, abortion and death in some cases. In contrast, no significant toxicity was observed when non-pregnant cynomolgus monkeys were given doses of imipenem-cilastatin sodium up to 180 mg/kg/day (subcutaneous injection). When doses of imipenem-cilastatin sodium (approximately 100 mg/kg/day or approximately 3 times the usual recommended daily human intravenous dose) were administered to pregnant cynomolgus monkeys at an intravenous infusion rate which mimics human clinical use, there was minimal maternal intolerance (occasional emesis), no maternal deaths, no evidence of teratogenicity, but an increase in embryonic loss relative to control groups.

Effects On Ability To Drive Or Operate Machinery
There are some adverse effects associated with this product that may affect some patients’ ability to drive or operate machinery (see Adverse Effects).

Adverse Effects
IMIPENEM+CILASTATIN RBX is generally well tolerated. In controlled clinical studies, imipenem-cilastatin was found to be tolerated as well as cefazolin, cephalothin, and cefotaxime. Adverse effects rarely require cessation of therapy and are generally mild and transient; serious adverse effects are rare. The most common adverse reactions have been local reactions. The following adverse effects have been reported during clinical studies and in post-marketing experience.

Local Reactions: Erythema, local pain and induration, thrombophlebitis.

Allergic Reactions/Skin: Rash, pruritus, urticaria, erythema multiforme, Stevens-Johnson syndrome, angioedema, toxic epidermal necrolysis (rarely), exfoliative dermatitis (rarely), candidiasis, fever, including fever induced by the medicine, anaphylactic reactions.

Gastrointestinal Reactions: Nausea, vomiting, diarrhoea, staining of teeth and/or tongue. In common with virtually all other broad spectrum antibiotics, pseudomembranous colitis has been reported. Blood: Eosinophilia, leukopaenia, neutropenia, including agranulocytosis, thrombocytopenia, thrombocytosis and decreased haemoglobin, pancytopenia and prolonged prothrombin time, have been reported. A positive direct Coombs test may develop in some individuals. Liver Function: Increases in serum transaminases, bilirubin and/or serum alkaline phosphatase; hepatic failure (rarely) hepatitis (rarely) and fulminant hepatitis (very rarely).

Renal Function: Oliguria/anuria, polyuria, acute renal failure (rarely). The role of IMIPENEM+CILASTATIN RBX in changes in renal function is difficult to assess, since factors predisposing to pre-renal azotaemia or to impaired renal function usually have been present.
Elevations in serum creatinine and blood urea nitrogen have been observed. Urine discoloration. This is harmless and should not be confused with haematuria.

*Nervous System/Psychiatric:* As with other beta-lactam antibiotics, CNS adverse experiences such as myoclonic activity, psychic disturbances, including hallucinations, confusional states, or seizures have been reported. Paresthesia, encephalopathy.

*Special Senses:* Hearing loss, taste perversion.

*Granulocytopenic Patients:* Medicine-related nausea and/or vomiting appear to occur more frequently in granulocytopenic patients than in non-granulocytopenic patients treated with IMIPENEM+CILASTATIN RBX.

*Other:* Bacterial or fungal superinfections.

**Additional Adverse Effect**
For the following adverse effects, a causal relationship has not been established.

*Gastrointestinal:* Haemorrhagic colitis, gastroenteritis, abdominal pain, glossitis, tongue papillar hypertrophy, heartburn, pharyngeal pain, increased salivation.

*Central Nervous System:* Dizziness, somnolence, vertigo, headache.

*Cardiovascular:* Hypotension, palpitations, tachycardia.

*Skin:* Flushing, cyanosis, hyperhidrosis, skin texture changes, pruritus vulvae.

*Body As A Whole:* Polyarthritis, asthenia/weakness.

*Blood:* Haemolytic anaemia, bone marrow depression.

**Interactions**
Generalised seizures have been reported in patients who received ganciclovir and imipenem-cilastatin. These medicines should not be used concomitantly unless the potential benefits outweigh the risks.

Also see Stability Section.

Decreases in serum valproic acid levels that may fall below the therapeutic range, have been reported in patients co-administered sodium valproate with carbapenem agents, including imipenem. The significant reductions in serum valproic acid levels (60% - 100%) have been reported within two days of other carbapenem administration and may lead to inadequate seizure control. Due to the rapid onset and the extent of the decrease in serum levels, co-
administration of carbapenem agents in patients stabilised on sodium valproate is not considered to be manageable and should therefore be avoided. If administration of IMIPENEM+CILASTATIN RBX is necessary, alternative or supplemental anti-convulsant therapy should be considered.

Overdosage
No specific information is available on the treatment of overdosage with IMIPENEM+CILASTATIN RBX. Imipenem-cilastatin sodium is haemodialysable. However, usefulness of this procedure in the overdosage setting is unknown.

Actions
Cilastatin is a competitive, reversible and specific inhibitor of dehydropeptidase-I enzyme, the renal enzyme which metabolises and inactivates imipenem. It is devoid of intrinsic antibacterial activity and does not affect the antibacterial activity of imipenem.

Imipenem is a beta-lactam antibiotic belonging to the thienamycin group. It is a potent inhibitor of bacterial cell wall synthesis and is bactericidal against a broad spectrum of pathogens - Gram-positive and Gram-negative, aerobic and anaerobic. Imipenem-cilastatin shares with the new cephalosporins and penicillins a broad spectrum of activity against Gram-negative species, but is unique in retaining the high potency against Gram-positive species, previously associated only with earlier narrow-spectrum beta-lactam antibiotics. The spectrum of activity of imipenem-cilastatin includes Pseudomonas aeruginosa, Staphylococcus aureus, Enterococcus faecalis and Bacteroides fragilis, a diverse group of problem pathogens commonly resistant to other antibiotics. Imipenem-cilastatin is resistant to degradation by bacterial beta-lactamases, which makes it active against a high percentage of organisms such as Pseudomonas aeruginosa, Serratia spp., and Enterobacter spp. which are inherently resistant to most beta-lactam antibiotics. The antibacterial spectrum of Imipenem-cilastatin is broader than that of any other antibiotic studied, and includes virtually all clinically significant pathogens. Organisms against which imipenem-cilastatin is usually active in vitro include:

Gram-Negative Aerobes

Achromobacter spp.
Acinetobacter spp. (formerly Mima-Herellea)
Aeromonas hydrophilia
Alcaligenes spp.
Bordetella bronchicanis
Bordetella bronchiseptica
Bordetella pertussis
Brucella melitensis
Burkholderia pseudomallei (formerly Pseudomanas pseudomallei)
Burkholderia stutzeri (formerly Pseudomanas stutzeri)
Campylobacter spp.
Capnocytophaga spp.
Citrobacter spp.
Citrobacter freundii
*Citrobacter koseri* (formerly *Citrobacter diversus*)
*Eikenella corrodens*
*Enterobacter* spp.
*Enterobacter aerogenes*
*Enterobacter agglomerans*
*Enterobacter cloacae*
*Escherichia coli*
*Gardnerella vaginalis.*
*Haemophilus ducreyi*
*Haemophilus influenzae* (including beta lactamase-producing strains)
*Haemophilus parainfluenzae*
*Hafnia alvei Klebsiella* spp.
*Klebsiella oxytoca*
*Klebsiella ozaenae*
*Klebsiella pneumoniae*
*Moraxella* spp.
*Morganella morganii* (formerly *Proteus morganii*)
*Neisseria gonorrhoeae* (including penicillinase-producing strains)
*Neisseria meningitides*
*Pasteurella* spp.
*Pasteurella multocida*
*Plesiomonas shigelloides*
*Proteus* spp.
*Proteus mirabilis*
*Proteus vulgaris*
*Providencia* spp.
*Providencia alcalifaciens*
*Providencia rettgeri* (formerly *Proteus rettgeri*)
*Providencia stuartii*
*Pseudomonas* spp**
*Pseudomonas aeruginosa*
*Pseudomonas fluorescens*
*Pseudomonas putida*
*Salmonella* spp.
*Salmonella typhi* *Serratia* spp.
*Serratia proteamaculans* (formerly *Serratia liquefaciens*)
*Serratia marcescens*
*Shigella* spp.
*Yersinia* spp. (formerly *Pasteurella*)
*Yersinia enterocolitica*
*Yersinia pseudotuberculosis*
**Stenotrophomonas maltophilia** (formerly *Xanthomonas maltophilia*, formerly *Pseudomonas maltophilia*) and some strains of *Burkholderia cepacia* (formerly *Pseudomonas cepacia*) are generally not susceptible to imipenem-cilastatin

**Gram-Positive Aerobes**
*Bacillus* spp.
*Enterococcus faecalis*
Erysipelothrix rhusiopathiae  
Listeria monocytogenes  
Nocardia  
Pediococcus  
*Staphylococcus aureus* (including penicillinase-producing strains)  
*Staphylococcus epidermidis* (including penicillinase-producing strains)  
*Staphylococcus saprophyticus*  
*Streptococcus agalactiae*  
*Streptococcus Group C*  
*Streptococcus Group G*  
*Streptococcus pneumoniae*  
*Streptococcus pyogenes*  
Viridans group streptococci (including alpha and gamma haemolytic strains)  
*Enterococcus faecium* and methicillin-resistant staphylococci are not susceptible to imipenem-cilastatin.

**Gram-Negative Anaerobes**

- *Bacteroides* spp.  
- *Bacteroides distasonis*  
- *Bacteroides fragilis*  
- *Bacteroides ovatus*  
- *Bacteroides thetaiotaomicron*  
- *Bacteroides uniformis*  
- *Bacteroides vulgatus*  
- *Bilophila wadsworthia*  
- *Fusobacterium* spp.  
- *Fusobacterium necrophorum*  
- *Fusobacterium nucleatum*  
- *Porphyromonas asaccharolytica* (formerly *Bacteroides asaccharolyticus*)  
- *Prevotella bivia* (formerly *Bacteroides bivius*)  
- *Prevotella disiens* (formerly *Bacteroides disiens*)  
- *Prevotella intermedia* (formerly *Bacteroides intermedius*)  
- *Prevotella melaninogenica* (formerly *Bactoeroides melaninogenicus*)  
- *Veillonella* spp.

**Gram-Positive Anaerobes**

- *Actinomyces* spp.  
- *Bifidobacterium* spp.  
- *Clostridium* spp.  
- *Clostridium perfringens*  
- *Eubacterium* spp.  
- *Lactobacillus* spp.  
- *Mobiluncus* spp.  
- *Microaerophilic streptococcus*  
- *Peptococcus* spp.  
- *Peptostreptococcus* spp.  
- *Propionibacterium* spp. (including *P. acnes*)

**Other**

- *Mycobacterium fortuitum*  
- *Mycobacterium smegmatis*
In vitro tests show imipenem to act synergistically with amino-glycoside antibiotics against some isolates of *Pseudomonas aeruginosa*.

Imipenem is not active against mycoplasma or chlamydia.

**Susceptibility Testing**

Clinical and Laboratory Standards Institute (CLSI) (Formerly NCCLS) - Methods of Susceptibility Testing

**SUSCEPTIBILITY TESTS**

When available, the results of *in vitro* susceptibility tests should be provided to the physician as periodic reports which describe the susceptibility profile of nosocomial and community-acquired pathogens. These reports should aid the physician in selecting the most effective antimicrobial.

Dilution Techniques:
Quantitative methods are used to determine antimicrobial minimum inhibitory concentrations (MICs). These MICs provide estimates of the susceptibility of bacteria to antimicrobial compounds. The MICs should be determined using a standardised procedure. Standardised procedures are based on a dilution method† (broth or agar) or equivalent with standardised inoculum concentrations and standardised concentrations of imipenem powder. The MIC values should be interpreted according to criteria provided in Table 5.

Diffusion Techniques: Quantitative methods that require measurement of zone diameters also provide reproducible estimates of the susceptibility of bacteria to antimicrobial compounds.

One such standardised procedure†† requires the use of standardised inoculum concentrations. This procedure uses paper disks impregnated with 10 mcg imipenem to test the susceptibility of microorganisms to imipenem. The disk diffusion interpretive criteria are provided in Table 5.

Anaerobic Techniques: For anaerobic bacteria, susceptibility to imipenem as MICs can be determined by a standardised test method†††,§. The MIC values obtained should be interpreted according to the criteria provided in Table 5.

Table 5
CLSI Interpretive Susceptibility Criteria for Imipenem

a The current absence of data on resistant strains precludes defining any category other than “susceptible”. If strains yield MIC results other than susceptible, they should be submitted to a reference laboratory for further testing.

b Streptococcus pneumoniae that are susceptible to penicillin by oxacillin disk (1-mcg oxacillin disk zone diameter ≥20 mm) or by penicillin MIC (penicillin MIC ≤0.06 mcg/mL) can be considered susceptible to imipenem. Disk diffusion testing with imipenem is not recommended as there are no interpretive criteria. Isolates with 1-mcg oxacillin zone diameter ≤19 mm should be tested against imipenem using an MIC method.

c Streptococcus spp other than S. pneumoniae that are susceptible to penicillin (10-units penicillin disk zone diameter ≥24 mm [beta haemolytic streptococci only] or penicillin MIC ≤0.12 mcg/mL [beta haemolytic streptococci and viridans group] can be considered susceptible to imipenem. There are no CLSI interpretive criteria for MIC testing of beta haemolytic Streptococcus spp or viridans group Streptococci against imipenem.

d These interpretive standards are applicable to the broth microdilution procedure using Haemophilus Test Medium (HTM) inoculated with a direct colony suspension and incubated in ambient air at 35°C for 20-24 hrs.

e These interpretive standards are applicable only to agar dilution using Brucella agar supplemented with haemin, vitamin K1 and 5% defibrinated or laked sheep blood inoculated with a direct colony suspension or a 6- to 24-hour fresh culture in enriched thioglycollate medium and incubated in an anaerobic jar or chamber at 35-37°C for 42-48 hrs.
A report of “Susceptible” indicates that the pathogen is likely to be inhibited if the antimicrobial compound in blood reaches the concentrations usually achievable. A report of “Intermediate” indicates that the result should be considered equivocal, and, if the microorganism is not fully susceptible to alternative, clinically feasible drugs, the test should be repeated. This category implies possible clinical applicability in body sites where the drug is physiologically concentrated or in situations where high dosage of drug can be used. This category also provides a buffer zone which prevents small uncontrolled technical factors from causing major discrepancies in interpretation. A report of “Resistant” indicates that the pathogen is not likely to be inhibited if the antimicrobial compound in the blood reaches the concentrations usually achievable; other therapy should be selected.

Quality Control:
Standardised susceptibility test procedures require the use of quality control microorganisms to control the technical aspects of the test procedures. Standard imipenem powder should provide the following range of values noted in Table 6. Quality control microorganisms are specific strains of organisms with intrinsic biological properties. QC strains are very stable strains which will give a standard and repeatable susceptibility pattern. The specific strains used for microbiological quality control are not clinically significant.

† This organism is used for quality control of susceptibility testing of *Streptococcus pneumoniae* and *Streptococcus* spp.
‡ These quality control ranges are applicable to *Streptococcus pneumoniae* ATCC 49619 tested by broth microdilution using cation-adjusted Mueller-Hinton broth with 2 to 5% lysed horse blood inoculated with a direct colony suspension and incubated in ambient air at 35°C for 20-24 hrs.
§ These quality control ranges are applicable to *Haemophilus influenzae* ATCC 49766 tested by the broth microdilution procedure using *Haemophilus* Test Medium (HTM) inoculated with a direct colony suspension and incubated in ambient air at 35°C for 20-24 hrs.
¶ These quality control ranges are applicable to *Haemophilus influenzae* ATCC 49247 tested by disk diffusion using *Haemophilus* Test Medium
(HTM) agar inoculated with a direct colony suspension and incubated in 5% CO₂ at 35°C for 16-18 hrs.

These quality control ranges are applicable only to agar dilution using *Brucella* agar supplemented with haemin, vitamin K1 and 5% defibrinated or laked sheep blood inoculated with a direct colony suspension or a 6- to 24-hour fresh culture in enriched thioglycollate medium and incubated in an anaerobic jar or chamber at 35-37°C for 42-48 hrs.

**Pharmacokinetics**

**Imipenem**

In normal volunteers, intravenous infusion of imipenem-cilastatin over 20 minutes resulted in peak plasma levels of imipenem ranging from 21 - 58 mcg/mL for the 500 mg dose, and from 41 - 83 mcg/mL for the 1000 mg dose. The mean peak plasma levels of imipenem following the 500 and 1000 mg doses were 39 and 66 mcg/mL, respectively. At these doses, plasma levels of imipenem antimicrobial activity decline to below 1 mcg/mL in 4 - 6 hours. The plasma half-life of imipenem was one hour. Approximately 70% of the administered antibiotic was recovered intact in the urine within 10 hours, and no further urinary excretion of the medicine was detectable. Urine concentrations of imipenem exceeded 10 mcg/mL for up to 8 hours after a 500 mg dose of imipenem-cilastatin.

The remainder of the administered dose was recovered in the urine as antibacterially inactive metabolites, and faecal elimination of imipenem is essentially nil.

No accumulation of imipenem in plasma or urine has been observed with regimens of imipenem-cilastatin administered as frequently as every 6 hours in patients with normal renal function. Concomitant administration of imipenem-cilastatin and probenecid resulted in minimal increases in the plasma levels and plasma half-life of imipenem. The urinary recovery of active (non metabolised) imipenem decreased to approximately 60% of the dose when imipenem-cilastatin was administered with probenecid.

When administered alone, imipenem is metabolised in the kidneys by dehydropeptidase-I. Individual urinary recoveries of metabolites ranged from 5 to 40%, with an average recovery of 15-20% in several studies.

The binding of imipenem to human serum proteins is approximately 20%.

During the laboratory evaluation of imipenem as a single entity, generally low urinary recovery of the antibiotic was found in a number of species, including the chimpanzee, and this was subsequently confirmed in humans also. Metabolism was shown to occur primarily in the kidney, affecting the secreted and filtered fraction of the antibiotic after its clearance from the blood. The major pathway of metabolism of imipenem in the kidney is by hydrolysis of the beta-lactam ring by a renal dipeptidase (EC.3.4.13.11). This enzyme is also known as dehydropeptidase-I (DHP-I) and is localised on the luminal (brush border) surface of the proximal renal tubular epithelium. Thus, the enzyme has access to the antibiotic both in the glomerular filtrate and during the transcellular secretory process. In man, urinary recovery of metabolites ranged from 5 to 40% of the administered dose, while good systemic persistence and blood levels were unaffected by metabolism in the kidney.

**Cilastatin**

Peak plasma levels of cilastatin, following a 20-minute intravenous infusion of imipenem-cilastatin, ranged from 21 to 55 mcg/mL for the 500 mg dose and from 56 to 88 mcg/mL for the 1000 mg dose. The mean peak plasma levels of cilastatin following the 500 and 1000 mg doses were 42 and 72 mcg/mL respectively. The plasma half-life of cilastatin is approximately one hour. Approximately 70-80% of the dose of cilastatin was recovered unchanged in the urine as the parent medicine within 10 hours of administration of imipenem-cilastatin. No further cilastatin appeared in the urine thereafter. Approximately 10% was found as the N-acetyl metabolite, which has inhibitory activity against dehydropeptidase comparable to that of the parent medicine. Activity of dehydropeptidase-I in the kidney returns to normal levels shortly after the elimination of cilastatin from the bloodstream.

Concomitant administration of imipenem-cilastatin and probenecid doubled the plasma level and half-life of cilastatin, but had no effect on urinary recovery of cilastatin.

The binding of cilastatin to human serum proteins is approximately 40%.
Low urinary tract bioavailability of imipenem is avoided by co-administration of cilastatin, a potent inhibitor of DHP-I isolated from a number of animal species.

The inhibition is competitive and freely reversible. Cilastatin did not significantly inhibit the activity of four other zinc metalloenzyme peptidases, including angiotensin converting enzyme. Cilastatin is devoid of antimicrobial activity per se, and has no significant effect on the antimicrobial activity of imipenem.

**Pharmaceutical Precautions**

Store below 25°C (See also Dosage and Administration section).

**Medicine Classifications**

Prescription medicine

**Package Quantities**

IMIPENEM+CILASTATIN RBX Powder for Solution for Infusion is available in a 30 mL "vial" which contains 500 mg Imipenem and 500 mg Cilastatin is a Type 1 clear glass vial with grey bromothymol rubber plug and polypropylene flip off seal.

Pack size: 1 vial

**Further Information**

**Imipenem**

The thienamycins are distinguished by novel structural features, the most important of which is the substitution of a methylene (-CH2-) group for the sulphur atom contained in the ring systems of most beta-lactam antibiotics. This substitution makes imipenem more reactive toward proteins in the bacterial cell wall and, therefore, more potent in its bactericidal effect. In further contrast to the penicillins and cephalosporins, the hydroxyethyl side chain of imipenem is attached to the beta-lactam ring in a trans orientation, and this unusual configuration endows imipenem with an unusually high stability to bacterial beta-lactamases. The chemical name of imipenem is [5R-[5α,6α(R*)]-6-(1-hydroxyethyl)-3-[[2-[(iminomethyl) amino]ethyl] thio]-7-oxo-1-azabicyclo[3.2.0]hept-2-ene-2-carboxylic acid monohydrate. The empirical formula of imipenem is C12H17N3O4S.H2O and the molecular weight is 317.37. It is a light tan to white, nonhygroscopic, ultraviolet light-sensitive, crystalline compound which is sparingly soluble in water, and slightly soluble in methanol. Imipenem, also referred to as N-formimidoyl thienamycin monohydrate, is a semi-synthetic derivative of thienamycin, the parent compound produced by the filamentous bacterium *Streptomyces cattleya*. The structural formula of imipenem is:
Cilastatin sodium
Cilastatin sodium is a competitive, reversible and specific inhibitor of dehydropeptidase-I, the renal enzyme which metabolises and inactivates imipenem. It is devoid of intrinsic antibacterial activity and does not affect the antibacterial activity of imipenem. The chemical name of the sodium salt of cilastatin is \([R\{R^*, S^*-(Z)\}]\)-7-[(2-amino-2-carboxyethyl)thio]-2-[[2,2-dimethylcyclopropyl]carbonyl] amino]-2-heptenoic acid, monosodium salt. The empirical formula of cilastatin sodium is C16H25N2NaO5S and the molecular weight is 380.44. It is an off-white to yellowish-white, hygroscopic, amorphous compound which is very soluble in water or methanol. The structural formula of cilastatin sodium is:
