NEW ZEALAND DATA SHEET

1. PRODUCT NAME

KETALAR®
ketamine hydrochloride

2. QUALITATIVE AND QUANTITATIVE COMPOSITION

It is formulated as an acid (pH 3.5 to 5.5) solution for intravenous or intramuscular injection in concentrations containing the equivalent of 100 mg ketamine base per millilitre.

For the full list of excipients see section 6.1.

3 PHARMACEUTICAL FORM

Solution for intravenous or intramuscular injection.

4 CLINICAL PARTICULARS

4.1 Therapeutic Indications

KETALAR® is recommended:

1. as the sole anaesthetic agent for diagnostic and surgical procedures that do not require skeletal muscle relaxation. KETALAR® is best suited for short procedures and it can be used with additional doses, for longer procedures;

2. for the induction of anaesthesia prior to the administration of other general anaesthetic agents;

3. to supplement low-potency agents, such as nitrous oxide.
4.2 Dose and method of administration

Pre-Operative Preparation

1. While vomiting has been reported following KETALAR® administration, airway protection is usually afforded because of active laryngeal-pharyngeal reflexes. However, because these reflexes may also be diminished by supplementary anaesthetics or muscle relaxants, the possibility of aspiration must be considered. KETALAR® is recommended for use in the patient whose stomach is not empty only when, in the judgement of the medical practitioner, the benefits of the drug outweigh the possible risks.

2. Atropine, hyoscine or other 'drying' agents should be given at an appropriate interval prior to induction.

Dosage

As with other general anaesthetic agents, the individual response to KETALAR® is somewhat varied depending on the dose, route of administration and age of patient, so that the dosage recommended cannot be absolutely determined in a fixed manner. The drug should be titrated against the patient's requirements.

Onset and Duration

Because of rapid induction following the initial intravenous injection, the patient should be in a supported position during administration. The onset of action of KETALAR® is rapid; an intravenous dose of 2 mg/kg of body weight usually produces surgical anaesthesia within 30 seconds after injection, with the anaesthetic effect usually lasting 5 to 10 minutes. If a longer effect is desired, additional increments can be administered intravenously or intramuscularly to maintain anaesthesia without producing significant cumulative effect.

From experience, intramuscular doses (primarily in children, in a range of 9 to 13 mg/kg) usually produce surgical anaesthesia within 3 to 4 minutes following administration, with the anaesthetic effect usually lasting 12 to 25 minutes.

Induction

Intravenous route: the initial dose of KETALAR® administered intravenously may range from 1 mg/kg to 4.5 mg/kg. The average amount required to produce 5 to 10 minutes of surgical anaesthesia has been 2 mg/kg.

NOTE

The 100 mg/mL concentration of KETALAR® should not be injected intravenously without appropriate dilution. It is recommended the drug be diluted with an equal volume of either sterile water for injection, normal saline or, 5% glucose in water.

Rate of administration: it is recommended that KETALAR® be administered slowly (over a period of 60 seconds). More rapid administration may result in respiratory depression and enhanced pressor response.
Intramuscular route: the initial dose of KETALAR® administered intramuscularly ranges from 6.5 to 13 mg/kg. A dose of 10 mg/kg will usually produce 12 to 25 minutes of surgical anaesthesia.

If the ketamine dose is augmented with diazepam, the two drugs must be given separately. Do not mix ketamine and diazepam in the same syringe or infusion flask.

**Dosage in Hepatic Insufficiency**

Dose reductions should be considered in patients with cirrhosis or other types of liver impairment (see section 4.4).

**Maintenance of Anaesthesia**

Increments of one half to the full induction dose may be repeated, as needed, for maintenance of anaesthesia. However it should be noted that involuntary and tonic-clonic movements of extremities might occur during the course of anaesthesia. These movements do not imply a level of attenuated anaesthesia and are not indicative of the need for additional doses of the anaesthetic. It should be recognised that the greater the total dose of KETALAR administered, the longer will be the time to complete recovery.

### 4.3 Contraindications

KETALAR® is contraindicated in patients with any condition in which a significant elevation of blood pressure would be hazardous such as: severe cardiovascular disease, heart failure, severe or poorly controlled hypertension, recent myocardial infarction, history of stroke, cerebral trauma, intracerebral mass or haemorrhage. Ketamine is also contraindicated in those who have shown hypersensitivity to the drug or its components.

### 4.4 Special warnings and precautions for use

1. KETALAR® should be used by or under the direction of medical practitioners experienced in administering general anaesthetics and in maintenance of an airway and in the control of respiratory support.

2. Barbiturates and KETALAR®, being chemically incompatible because of precipitate formation, should not be injected from the same syringe.

3. Prolonged recovery time may occur if barbiturates and/or narcotics are used concurrently with KETALAR®.

4. Post-operative confusional states may occur during the recovery period (see section 4.4 - Emergence Reaction).

5. Because pharyngeal and laryngeal reflexes are usually active, KETALAR should not be used alone in surgery or diagnostic procedures of the pharynx, larynx or bronchial tree. Mechanical stimulation of the pharynx should be avoided, whenever possible, if
KETALAR is used alone. Muscle relaxants with proper attention to respiration, may be required in both of these instances.

6. Resuscitative equipment should be ready for use.

7. The intravenous dose should be administered over a period of 60 seconds. More rapid administration may result in respiratory depression or apnoea and enhanced pressor response.

8. In surgical procedures involving visceral pain pathways, KETALAR® should be supplemented with an agent which obtunds visceral pain.

10. An increase in cerebrospinal fluid pressure has been reported following administration of KETALAR®. Use with extreme caution in patients with pre-anaesthetic elevated cerebrospinal fluid pressure.

11. In patients with significant renal or hepatic impairment, the elimination of ketamine could potentially be delayed. Dose reductions should be considered in patients with cirrhosis or other types of liver impairment.

12. Patients should be cautioned that driving an automobile, operating machinery or engaging in other hazardous activities should not be undertaken for 24 hours or more (depending on dose and other drugs employed) after anaesthesia.

13. Use with caution in patients with increased intraocular pressure (eg. glaucoma) because the pressure may increase significantly after a single dose of ketamine.

14. Use with caution in patients with neurotic traits or psychiatric illness (eg. schizophrenia and acute psychosis).

15. Use with caution in patients with acute intermittent porphyria.

16. Use with caution in patients with seizures.

17. Use with caution in patients with hyperthyroidism or patients receiving thyroid replacement (increased risk of hypertension and tachycardia).

18. Use with caution in patients with pulmonary or upper respiratory infection (ketamine sensitises the gag reflex, potentially causing laryngospasm).

19. Use with caution in patients with intracranial mass lesions, a presence of head injury, globe injuries, or hydrocephalus.

Emergence Reaction

Treatment-emergent adverse reactions have occurred in approximately 12% of patients. The psychological manifestations vary in severity between pleasant dream-like states, vivid imagery, hallucinations, nightmares or illusions and delirium (often consisting of dissociative or floating sensations). In some cases, these states have been accompanied by confusion, excitement and
irrational behaviour which a few patients recall as an unpleasant experience. The duration ordinarily lasts no more than a few hours; in a few cases, however, recurrences have taken place up to 24 hours post-operatively. No residual psychological effects are known to have resulted from use of Ketalar.

The incidence of these treatment-emergent adverse events is least in the young (15 years of age or less) and elderly (over 65 years of age) patient. Also they are less frequent when the drug is given intramuscularly. These reactions may be reduced if verbal, tactile and visual stimulation of the patient is minimised during the recovery period.

This does not preclude the monitoring of vital signs. In addition, the use of a small hypnotic dose of a short-acting or ultra-short-acting barbiturate may be required to terminate a severe treatment-emergent adverse reaction. The incidence of emergence reactions is reduced as experience with the drug is gained. When Ketalar is used on an out-patient basis, the patient should not be released until recovery of anaesthesia is complete and should be accompanied by a responsible adult at discharge.

**Cardiovascular**

Because of the substantial increase in myocardial oxygen consumption, ketamine should be used with caution in patients with hypovolemia, dehydration, or cardiac disease, especially coronary artery disease (e.g., congestive heart failure, myocardial ischaemia, and myocardial infarction). In addition ketamine should be used with caution in patients with mild-to-moderate hypertension and tachyarrhythmias.

Cardiac function should be continually monitored during the procedure in patients found to have hypertension or cardiac decompenation.

**Abuse Potential**

Ketamine has been reported being used as a drug of abuse. Reports suggest that ketamine produces a variety of symptoms including, but not limited to, flashbacks, hallucinations, dysphoria, anxiety, insomnia, or disorientation. Ketamine dependence and tolerance may develop in individuals with a history of drug abuse or dependence. Therefore, ketamine should be prescribed and administered with caution.

**4.5 Interaction with other medicines and other forms of interaction**

Halogenated hydrocarbon inhalational anaesthetics may prolong the half-life of ketamine; recovery from anaesthesia may be prolonged following concurrent use. Concurrent use of ketamine (especially in high doses or when rapidly administered) with halogenated anaesthetics can increase the risk of developing bradycardia, hypotension, or decreased cardiac output.

Diazepam is known to increase the half-life of ketamine and prolongs its pharmacodynamic effects. Dose adjustments may therefore be needed.

Sympathomimetics (directly or indirectly acting) and vasopressin may enhance the sympathomimetic effects of ketamine.
Prolonged recovery time may occur if barbiturates and/or narcotics are used concurrently with ketamine.

Benzodiazepines may prolong the half life of ketamine; recovery from anaesthesia may be prolonged following concurrent use.

Concomitant use with ergometrine may lead to an increase in blood pressure and co-administration of drugs with a hypertensive effect (e.g. ergometrine) should be avoided.

Sustained rises in arterial pressure have been reported in patients receiving concomitant ketamine and thyroxine.

Clinically significant reduction in seizure threshold may be observed in patients receiving concomitant ketamine and theophylline or aminophylline. Unpredictable extensor-type seizures have been reported with concurrent administration of these agents.

There is no information available on the interactions between ketamine and antihypertensive agents. However, given the marked increase in arterial pressure following administration of ketamine, cardiac function should be monitored (see section 4.4).

Barbiturates and KETALAR®, being chemically incompatible because of precipitate formation, should not be injected from the same syringe.

Ketamine is clinically compatible with the commonly used general and local anaesthetic agents when an adequate respiratory exchange is maintained.

Ketamine may potentiate the neuromuscular blocking effects of atracurium and tubocurarine, including respiratory depression with apnoea.

The use of ketamine with other central nervous system (CNS) depressants (e.g. ethanol, phenothiazines, sedating H₁-blockers, or skeletal muscle relaxants) can potentiate CNS depression and/or increase risk of developing respiratory depression. Reduced doses of ketamine may be required with concurrent administration of other anxiolytics, sedatives, and hypnotics.

Ketamine has been reported to antagonise the hypnotic effect of thiopental.

Patients taking thyroid hormones have an increased risk of developing hypertension and tachycardia when given ketamine.

Concomitant use of antihypertensive agents and ketamine increases the risk of developing hypotension.

**Effects on Laboratory Tests**

There is no information available regarding the possible effects of ketamine on clinical laboratory tests.
4.6 Fertility, pregnancy and lactation

Pregnancy
Category B3

Limited studies in animals have not shown that ketamine causes birth defects; however, it crosses the placenta. Histological changes in the heart (degeneration and oedema of cardiac muscle), liver (diffuse haemopoietic cell infiltration, parenchymal cell degeneration) and kidneys (proximal convoluted tubule degeneration) were observed in foetuses following administration of ketamine to pregnant rats during the period of organogenesis at doses similar to the maximum human dose, on a body surface area basis; a NOEL for these effects was not established. Ketamine administration to pregnant monkeys near term was associated with increased blood pCO₂ and a dose-dependent respiratory depression in neonates, at a dose about one sixteenth the maximum human dose on a body surface area basis.

With the exception of administration during surgery for abdominal delivery or vaginal delivery, no controlled clinical studies in pregnancy have been conducted. The safe use of ketamine in pregnancy has not been established, and such use is not recommended.

Breast-feeding
Ketamine is likely to be excreted in breast milk and therefore breastfeeding should be discontinued when ketamine is in use.

4.7 Effects on ability to drive and use machines

Patients should be cautioned that driving a car, operating hazardous machinery or engaging in hazardous activities should not be undertaken for 24 hours or more (depending upon the dosage of ketamine and consideration of other drugs employed) after anaesthesia. As appropriate, especially in cases where early discharge is possible, the duration of ketamine and other drugs employed during the conduct of anaesthesia should be considered.

4.8 Undesirable Effects

Cardiovascular
Blood pressure and pulse rate are frequently elevated following administration of KETALAR®. However, hypotension and bradycardia have been observed. Arrhythmia has also occurred.

Respiration
Although respiration is frequently stimulated, severe depression of respiration or apnoea may occur following rapid intravenous administration of high doses of KETALAR®. Laryngospasm and other forms of airway obstruction have occurred during KETALAR® anaesthesia.
Eye
Diplopia and nystagmus have been noted following KETALAR® administration. KETALAR® may also cause a slight elevation in intraocular pressure measurement.

Psychological (see section 4.4 - Emergence Reaction)

Neurological
In some patients, enhanced skeletal muscle tone may be manifested by tonic and clonic movements, sometimes resembling seizures (see section 4.2).

Gastrointestinal
Anorexia, nausea and vomiting have been observed. However this is not usually severe and allows the great majority of patients to take liquids by mouth shortly after regaining consciousness (see section 4.2). Hypersalivation has also been observed.

Abuse Potential (see section 4.4)

Immune System Disorders
Anaphylaxis has been observed.

General
Local pain and exanthema at the injection site have infrequently been reported. Transient erythema and/or morbilliform rash have also been reported.

Reporting of Suspected Adverse Reactions
Reporting suspected adverse reactions after authorisation of the medicine is important. It allows continued monitoring of the benefit/risk balance of the medicine. Healthcare professionals are asked to report any suspected adverse reactions https://nzphvc.otago.ac.nz/reporting/.

4.9 Overdose
Respiratory depression may occur with overdosage or too rapid rate of administration of KETALAR®, in which case, supportive ventilation should be employed. Mechanical support of respiration is preferred to administration of analeptics.

Ketamine has a wide margin of safety; several instances of unintentional administration of overdoses of KETALAR® (up to 10 times that usually required) have been followed by prolonged but complete recovery.
For advice on the management of overdose please contact the National Poisons Centre on 0800 POISON (0800 764766).

5 PHARMACOLOGICAL PROPERTIES

5.1 Pharmacodynamic properties

Actions

KETALAR® is a rapid-acting, general anaesthetic producing an anaesthetic state characterised by profound analgesia, normal pharyngeal-laryngeal reflexes, normal or slightly enhanced skeletal muscle tone, cardiovascular and respiratory stimulation, and occasionally, a transient and minimal respiratory depression.

A patent airway is maintained, partly by virtue of relatively unimpaired pharyngeal and laryngeal reflexes (see section 4.4).

The anaesthetic state produced by KETALAR® has been termed 'dissociative anaesthesia' in that it appears to selectively interrupt association pathways of the brain before producing somaesthetic sensory blockade. KETALAR® may selectively depress the thalamoneocortical system before significantly obtunding the more ancient cerebral centres and pathways (reticular-activating and limbic systems).

Elevation of blood pressure begins shortly after injection, reaches a maximum within a few minutes and usually returns to pre-anaesthetic values within 15 minutes after injection. The median peak rise has ranged from 20 to 25% of pre-anaesthetic values.

Clinical Studies

KETALAR® (ketamine as hydrochloride) has been studied in over 12,000 operative and diagnostic procedures involving over 10,000 patients from 105 separate studies. During the course of these studies, KETALAR® was administered as the sole agent, as induction for other general anaesthetic agents, or to supplement low potency agents. In these studies, the anaesthesia was rated either “excellent” or “good” by the anaesthetist and the surgeon at 90% and 93% respectively. In a second method of evaluation, the anaesthesia was rated “adequate” in at least 90% and “inadequate” in 10% or less of procedures. Specific areas of application have included the following:

1. debridement, painful dressings and skin grafting in burn patients as well as other superficial surgical procedures;
2. neurodiagnostic procedures such as pneumoencephalograms, ventriculograms, myelograms and lumbar punctures;
3. diagnostic and operative procedures of the eye, ear, nose and mouth including dental extractions;
4. diagnostic and operative procedures of the pharynx, larynx or bronchial tree;

    Note: muscle relaxants with proper attention to respiration, may be required (see section 4.4)

5. sigmoidoscopy and minor surgery of the anus and rectum and circumcision;

6. extraperitoneal procedures used in gynaecology, such as dilation and curettage;

7. orthopaedic procedures such as closed reductions, manipulations, femoral pinning, amputations and biopsies;

8. as an anaesthetic in poor-risk patients with depression of vital functions;

9. in procedures where the intramuscular route of administration is preferred;

10. in cardiac catheterisation procedures.

5.2 Pharmacokinetic properties

Absorption
Ketamine is rapidly absorbed following parenteral administration. Peak plasma levels averaged 0.75µg/ml and CSF levels were about 0.2µg/ml one hour after dosing. The plasma half-life is in the range of 2 to 4 hours. After IM administration (absorption half-life 2-17 minutes) it is up to 93 % bioavailable.

Distribution
Ketamine (as hydrochloride) is rapidly and extensively distributed throughout the body into highly perfused tissues including the brain. Mean volume of distribution is reported to range from approximately 1 to 3 L/kg, and the distribution half-life is approximately 7 to 11 minutes. Ketamine (as hydrochloride) is approximately 20-50% bound to plasma proteins. Ketamine is likely to be excreted in breast milk, but this is unlikely to be clinically relevant. The drug crosses the placenta in induction doses but in amounts that have no adverse effects on the neonate (see section 4.6).

Metabolism
Ketamine undergoes extensive hepatic metabolism. The biotranformation includes N-dealkylation to norketamine (metabolite I), hydroxylation of the cyclohexone ring (metabolites III and IV), conjugation with glucuronic acid and dehydration of the hydroxylated metabolites to form the cyclohexene derivative (metabolite II). Norketamine (metabolite I) has about 1/6 of the potency of ketamine and is formed at concentrations in the plasma similar to those of the parent compound.
Elimination
After intravenous bolus administration, ketamine shows a bi- or triexponential pattern of elimination. The alpha phase lasts about 45 minutes with a half-life of 10 to 15 minutes. This first phase, which represents the anaesthetic action of ketamine, is terminated by redistribution from the CNS to peripheral tissues and hepatic biotransformation to an active metabolite. The beta phase half-life is about 2.5 hours. About 90% of ketamine is excreted in the urine, mostly as metabolites, with only about 2 to 4% as the unchanged drug. Approximately 5% is recovered in the faeces. The renal clearance of ketamine hydrochloride is $15 \pm 5 \text{ mL/min/kg}$.

Paediatric Patients
Plasma half-life, clearance and volume of distribution (relative to body weight) are not significantly different between adults and children, although absorption following intramuscular injection is more rapid in the latter.

5.3 Preclinical safety data
Animal toxicology and/or pharmacology
Published studies in animals demonstrate that the use of anaesthetic and sedative agents that block NMDA receptors and/or potentiate GABA activity during the period of rapid brain growth or synaptogenesis results in widespread neuronal and oligodendrocyte cell loss in the developing brain and alterations in synaptic morphology and neurogenesis when administered at either high doses, or for prolonged periods, or both. Based on comparisons across species, the window of vulnerability to these changes is believed to correlate with exposures in the third trimester through the first several months of life, but may extend out to approximately 3 years of age in humans.

In primates, exposure to 3 hours of an anaesthetic regimen that produced a light surgical plane of anaesthesia did not increase neuronal cell loss, however, treatment regimens of 5 hours or longer increased neuronal cell loss. Data in rodents and in primates suggest that the neuronal and oligodendrocyte cell losses are associated with prolonged cognitive deficits in learning and memory.

In a published study conducted on rhesus monkeys, administration of an anaesthetic dose of ketamine for 24 hours on Gestation Day 122 increased neuronal apoptosis in the developing brain of the foetus. In other published studies, administration of either isoflurane or propofol for 5 hours on Gestation Day 120 resulted in increased neuronal and oligodendrocyte apoptosis in the developing brain of the offspring of rhesus macaques. With respect to brain development, this time period corresponds to the third trimester of gestation in the human. There are no data on pregnancy exposures in primates corresponding to periods prior to the third trimester in humans. The clinical significance of these findings is not clear; however, studies in juvenile animals suggest neuroapoptosis correlates with long-term cognitive deficits. Healthcare providers should balance the benefits of appropriate anaesthesia in pregnant women, neonates and young children who require procedures with the potential risks suggested by the nonclinical data.
6 PHARMACEUTICAL PARTICULARS

6.1 List of excipients
Contains not more than 0.1 mg/mL benzethonium chloride (phemerol) as a preservative.
KETALAR® injection also contains benzethonium chloride and water for injections.

6.2 Incompatibilities
Barbiturates and KETALAR®, being chemically incompatible because of precipitate formation, should not be injected from the same syringe.

6.3 Shelf life
36 months from date of manufacture stored at or below 30°C

6.4 Special precaution for storage
Store below 30°C.
KETALAR® injection should not be used if the solution is coloured and/or contains particulate matter.

6.5 Nature and contents of the container
KETALAR® 200 mg (base)/2 mL, 5 X 2 mL vials
KETALAR® 1000 mg (base)/10 mL, 5 X 10 mL vials. (not marketed)

6.6 Special precautions for disposal and other handling
This product is for one dose in one patient only. Discard any remaining contents.
