Name of Medicine
METALYSE®
Tenecteplase

Presentation
METALYSE 40 mg: 1 vial containing 8,000 units (40 mg) tenecteplase.
1 prefilled syringe containing 8 ml water for injection. (Not marketed)

METALYSE 50 mg: 1 vial contains 10,000 units (50 mg) tenecteplase.
1 prefilled syringe containing 10 ml water for injection.

White to off-white powder and solvent for solution for injection. Reconstitution results in a colourless to pale yellow, transparent, clear solution.

Uses
Actions
METALYSE pharmacotherapeutic group is Antithrombotic agent, ATC code: B01A D.

The active ingredient of METALYSE (tenecteplase) is a recombinant fibrin-specific plasminogen activator that is derived from native t-PA by modification at three sites of the protein structure. It binds to the fibrin component of the thrombus (blood clot) and selectively converts thrombus-bound plasminogen to plasmin, which degrades the fibrin matrix of the thrombus. Tenecteplase has a higher fibrin specificity and greater resistance to inactivation by its endogenous inhibitor (PAI-1) compared to native t-PA.

After administration of tenecteplase, dose dependent consumption of $\alpha_2$-antiplasmin (the fluid-phase inhibitor of plasmin) with consequent increase in the level of systemic plasmin generation have been observed. This observation is consistent with the intended effect of plasminogen activation. In comparative studies a less than 15% reduction in fibrinogen and a less than 25% reduction in plasminogen were observed in subjects treated with a maximum dose of tenecteplase (10,000 U, corresponding to 50 mg), whereas alteplase caused an approximately 50% decrease in fibrinogen and plasminogen levels. No clinically relevant antibody formation was detected at 30 days.

Patency rates from the phase I and II angiographic studies suggest that tenecteplase, administered as a single intravenous bolus, is effective in dissolving blood clots in the infarct-related artery of subjects experiencing acute myocardial infarction (AMI) on a dose related basis.

ASSENT 2 study
A large scale mortality trial (ASSENT 2) in approximately 17,000 patients showed that tenecteplase is therapeutically equivalent to alteplase in reducing mortality (6.2% for both treatments at 30 days) and that the use of tenecteplase is associated with a significantly lower incidence of non-intracranial bleedings (26.4% vs 28.9%, $p = 0.0003$). The reduction of the risk of bleeding is likely to be related to the increased fibrin specificity of tenecteplase and to its weight adapted regimen.

This translates into a significantly lower need of transfusions (4.3% vs. 5.5%, $P = 0.0002$). Intracranial haemorrhage occurred at a rate of 0.93% vs. 0.94% for tenecteplase and alteplase, respectively. In the 475 patients treated beyond 6 hours numerical differences in favour of tenecteplase were observed with regard to 30-day mortality (4.3% vs. 9.6%), stroke (0.4% vs. 3.3%) and ICH (0% vs. 1.7%).
**ASSENT 3 study**
The ASSENT 3 study aimed to optimise tenecteplase concomitant antithrombotic therapy towards both improving early patency rates and maintaining perfusion, mainly to overcome the paradoxical pro-coagulant effect arising from the release by clot lysis of trapped thrombin. Three different concomitant antithrombotic regimens were compared in 6,095 patients:
Full-dose tenecteplase + unfractionated heparin (UFH) versus full-dose tenecteplase + low molecular weight (LMW) heparin (enoxaparin) versus half-dose tenecteplase + unfractionated heparin + full dose abciximab.

UFH was used as recommended by AHA/ACC guidelines according to a full body-weight adapted low dose regimen as follows: A single IV bolus of 60 IU/kg (maximum 4000 IU) immediately followed by an intravenous infusion of 12 IU/kg/hr (maximum 1000 IU/hr) for the first 3 hours, thereafter according to aPTT monitoring for up to 48 hours to maintain aPTT at 50-70 seconds. 30-day mortality rates are respectively 6.0%, 5.4% and 6.6%, the in-hospital major bleeds (other than ICH) 2.16%, 3.04% and 4.32% and the intracranial haemorrhage 0.93%, 0.88% and 0.94%. The recommended ACC/AHA fully body-weight adjusted low dose unfractionated heparin regimen used in ASSENT 3 concomitantly with tenecteplase results in less systemic bleeding but similar ICH rates compared to the more aggressive unfractionated heparin regimen dosing used in ASSENT 2 without loss of efficacy.

**ASSENT 3 PLUS study**
ASSENT 3 PLUS, a satellite study of ASSENT 3, was designed to investigate the pre-hospital setting. The efficacy and safety of full-dose tenecteplase + unfractionated heparin versus full-dose tenecteplase + low molecular weight (LMW) heparin (enoxaparin) has been evaluated in 1639 patients. The study design and treatments dosage used are identical to those of the ASSENT 3 study. Pre-hospital reperfusion therapy with tenecteplase and UFH or enoxaparin allowed treatment within 2 hours of symptom onset in >50% of the patients with STEMI.

From ASSENT 3 and 3 PLUS studies, pre-hospital as well as in-hospital adjunctive therapy with enoxaparin reduced the incidence of ischemic complications as compared to adjunctive therapy with UFH: the incidence of 30-day efficacy composite endpoint (death, re-infarction, refractory ischaemia) was respectively 11.4% versus 15.4% in ASSENT 3 and 14.2% versus 17.4% in ASSENT 3 PLUS. However, in the pre-hospital setting, tenecteplase with enoxaparin at the dose used was associated with an increased risk of major bleeding and ICH in patients >75 years of age.

Coronary patency and limited clinical outcome data showed that AMI patients have been successfully treated later than 6 hours after symptom onset.

**ASSENT-4 PCI study**
The ASSENT-4 PCI study was designed to show if in 4000 patients with large myocardial infarctions pre-treatment with full dose tenecteplase and concomitant single bolus of up to 4,000 IU unfractionated heparin administered prior to primary Percutaneous Coronary Intervention (PCI) to be performed within 60 to 180 minutes leads to better outcomes than primary PCI alone. The trial was prematurely terminated with 1667 randomised patients due to a numerically higher mortality in the facilitated PCI group receiving tenecteplase. The occurrence of the primary endpoint, a composite of death or cardiogenic shock or congestive heart failure within 90 days, was significantly higher in the group receiving the exploratory regimen of tenecteplase followed by routine immediate PCI: 18.6% (151/810) compared to 13.4% (110/819) in the PCI only group, p=0.0045. This significant difference between the groups for the primary endpoint at 90 days was already present in-hospital and at 30 days. Numerically, all of the components of the clinical composite endpoint were in favour of the PCI only regimen: death: 6.7% versus 4.9% p=0.14; cardiogenic shock: 6.3% versus 4.8% p=0.19; congestive heart failure: 12.0% versus 9.2% p=0.06 respectively. The secondary endpoints re-infarction and repeat target vessel revascularisation were significantly increased in the group pre-treated with tenecteplase: reinfarction: 6.1% versus 3.7% p=0.0279; repeat target vessel revascularisation: 6.6% versus 3.4% p=0.0041.
The following adverse events occurred more frequently with tenecteplase prior to PCI: intracranial haemorrhage: 1% versus 0% p=0.0037; stroke: 1.8% versus 0% p<0.0001; major bleeds: 5.6% versus 4.4% p=0.3118; minor bleeds: 25.3% versus 19.0% p=0.0021; blood transfusions: 6.2% versus 4.2% p=0.0873; abrupt vessel closure: 1.9% versus 0.1% p=0.0001.

**STREAM study**
The STREAM study was designed to evaluate the efficacy and safety of a pharmaco-invasive strategy of early fibrinolytic treatment with tenecteplase and additional antiplatelet and anticoagulant therapy followed by angiography within 6-24 hours or rescue coronary intervention versus a strategy of standard primary PCI.

The study population consisted of patients with ST elevation acute myocardial infarction within 3 hours of onset of symptoms not able to undergo primary PCI within one hour of first medical contact.

A sample size of approximately 1000 patients per treatment group was planned for this exploratory study. After 382 patients had been enrolled (19.5% of the planned study population), the dose of the tenecteplase bolus was reduced by half for the patients ≥ 75 years because of a higher incidence of intracranial haemorrhage (ICH) in this sub-group.

1892 patients were randomised by means of an interactive voice response system. The primary endpoint, a composite of death or cardiogenic shock or congestive heart failure or re-infarction within 30 days was observed in 12.4% (116/939) of the pharmaco-invasive arm versus 14.3% (135/943) in the primary PCI arm (relative risk 0.86 (0.68-1.09)).

Single components of the primary composite endpoint for the pharmaco-invasive strategy versus primary PCI respectively were observed with the following frequencies:

</tbody>
</table>

* the incidences in both groups are those expected in STEMI patients treated by fibrinolytics or primary PCI (as observed in previous clinical studies).
** the incidence in the pharmaco-invasive group is as expected for fibrinolysis with Metalyse (as observed in previous clinical studies).

None of the differences between groups displayed in the above tables reached the threshold of statistical significance except for the incidence of total strokes and ICH, however the incidences in the pharmaco-invasive group were as observed in previous clinical studies.

After the dose reduction of tenecteplase by half in patients ≥ 75 years there was no further intracranial hemorrhage (0 of 97 patients) (95% CI: 0.0- 3.7) versus 8.1% (3 of 37 patients) (95% CI: 1.7- 21.9) prior to the dose reduction. The bounds of the confidence interval of the observed incidences prior and after dose reduction are overlapping.

In patients ≥ 75 years the observed incidence of the primary efficacy composite end point for the pharmaco-invasive strategy and primary PCI were as follows: before dose reduction 11/37 (29.7%) (95% CI: 15.9- 47.0) vs. 10/32 (31.3%) (95% CI: 16.1-50.0), after dose reduction: 25/97 (25.8%) (95% CI: 17.4-35.7) vs. 25/88 (24.8%) (95% CI: 19.3-39.0). In both groups the bounds of the confidence interval of the observed incidences prior and post dose reduction are overlapping.

**Pharmacokinetics**

*Absorption and distribution*

Tenecteplase is an intravenously administered recombinant protein that activates plasminogen. Following i.v. bolus administration of 30 mg tenecteplase in patients with acute myocardial infarction, the initially estimated tenecteplase plasma concentration was 6.45 ± 3.60 µg/mL (mean ± SD). The distribution phase represents 31% ± 22% to 69% ± 15% (mean ± SD) of the total AUC following the administration of doses ranges from 5 to 50 mg. Data on tissue distribution and elimination were obtained in studies with radioactively labelled tenecteplase in rats. The main organ to which tenecteplase distributed was the liver. It is not known whether and to which extent tenecteplase binds to plasma proteins in humans. The mean residence time (MRT) in the body is approximately 1 h and the mean (± SD) volume of distribution at the steady-state (Vss) ranged from 6.3 ± 2 L to 15 ± 7 L.
**Metabolism**
Tenecteplase is cleared from the circulation by binding to specific receptors in the liver followed by catabolism to small peptides. Binding to hepatic receptors is, however, reduced compared to native t-PA, resulting in a prolonged half-life.

**Elimination**
After single intravenous bolus injection of tenecteplase in patients with AMI, tenecteplase antigen exhibits biphasic elimination from the plasma. There is no dose dependent clearance of tenecteplase, in the therapeutic dose range. The initial, dominant half-life was 24 ± 5.5 (mean ± SD) min, which was 5 times longer than native t-PA. The terminal half-life was 129 ± 87 min, and plasma clearance was 119 ± 49 ml/min.

Increasing body weight resulted in moderate increase in tenecteplase clearance, and increasing age resulted in a slight decrease in clearance. Women exhibit a general lower clearance then men, but this can be explained by the generally lower body weight of women.

**Linearity/Non-Linearity**
The dose linearity analysis based on AUC suggested that tenecteplase exhibits non-linear pharmacokinetics in the dose range studied, i.e. 5 to 50 mg.

**Special populations**
Renal and hepatic impairment
Because elimination of tenecteplase is through the liver, it is not expected that renal dysfunction will affect the pharmacokinetics of METALYSE. This is also supported by animal data. However, the effect of renal and hepatic dysfunction on pharmacokinetics of tenecteplase in humans has not been specifically investigated.

**Indications**
METALYSE is indicated for the thrombolytic treatment of the acute phase of myocardial infarction (AMI). Treatment should be initiated as soon as possible after symptom onset. Treatment can be initiated within 12 hours of symptom onset.

**Dosage and Administration**
METALYSE should be administered on the basis of body weight, with a maximum dose of 10,000 units (50 mg tenecteplase). The volume required to administer the correct dose can be calculated from the following scheme:

<table>
<thead>
<tr>
<th>Patients' body weight category (kg)</th>
<th>Tenecteplase (U)</th>
<th>Tenecteplase (mg)</th>
<th>Volume of reconstituted solution (ml)</th>
</tr>
</thead>
<tbody>

<td>10</td>
</tr>
</tbody>
</table>

The required dose should be administered as a single intravenous bolus over 5 to 10 seconds.

A pre-existing intravenous line, which has been used for administration of 0.9% sodium chloride solution only, may be used for administration of METALYSE. If a line is used, this line should be flushed after METALYSE injection for proper delivery.

METALYSE is incompatible with dextrose solution.

METALYSE should not be mixed with other drugs, neither in the same infusion-vial nor the same venous line (not even with heparin).
Adjunctive Therapy
Antithrombotic adjunctive therapy is recommended according to the current international guidelines for the management of patients with ST-elevation myocardial infarction.

For coronary intervention please refer to Warnings and Precautions.

Contraindications
METALYSE is contraindicated in the following situations because thrombolytic therapy is associated with a higher risk of bleeding:

- Significant bleeding disorder either at present or within the past 6 months, known haemorrhagic diathesis.
- Patients receiving effective oral anticoagulant treatment, e.g. warfarin sodium (INR > 1.3). Refer to Warnings and Precautions - Bleeding
- Any history of central nervous damage (i.e. neoplasm, aneurysm, intracranial or spinal surgery).
- Severe uncontrolled arterial hypertension.
- Major surgery, biopsy of parenchymal organ, or significant trauma within the past 2 months (this includes any trauma associated with the current AMI), recent trauma to the head or cranium.
- Prolonged or traumatic cardiopulmonary resuscitation (> 2 minutes) within the past 2 weeks.
- Severe hepatic dysfunction, including hepatic failure, cirrhosis, portal hypertension (oesophageal varices) and active hepatitis.
- Active peptic ulceration.
- Arterial aneurysm and known arterial/venous malformation.
- Neoplasm with increased bleeding risk.
- Acute pericarditis and/or subacute bacterial endocarditis
- Acute pancreatitis
- Hypersensitivity to the active substance tenecteplase, gentamicin (a trace residue from the manufacturing process) or to any of the excipients.
- Haemorrhagic stroke or stroke of unknown origin at any time
- Ischaemic stroke or transient ischaemic attack (TIA) in the preceding 6 months

Warnings and Precautions
The decision to treat a patient with acute myocardial infarction with METALYSE should be taken under the consultation of a physician experienced in the use of thrombolytic treatment and with the facilities to monitor that use. This does not preclude the pre-hospital use of METALYSE. As with other thrombotics, it is recommended that when METALYSE is administered standard resuscitation equipment and medication be available in all circumstances.

Coronary intervention
Transfer to a coronary intervention capable facility for adjunctive Percutaneous Coronary Intervention (PCI):
Patients receiving METALYSE as primary coronary recanalization treatment should be transferred without delay to a coronary intervention capable facility for angiography and timely coronary intervention within 6-24 hours or earlier if medically indicated (please refer to Actions).

Primary Percutaneous Coronary Intervention (PCI)
If primary PCI is scheduled according to the current relevant treatment guidelines, METALYSE as administered in the ASSENT-4 PCI study (please refer to section "Actions") should not be given.
**Bleeding**
Although METALYSE is characterised by a significantly lower incidence of extracranial bleeding as compared to ACTILYSE®, bleeding can occur. The most common complication encountered during METALYSE therapy is bleeding. The concomitant use of heparin anticoagulation may contribute to bleeding. As fibrin is lysed during METALYSE therapy, bleeding from recent puncture sites may occur. Therefore, thrombolytic therapy requires careful attention to all possible bleeding sites (including those following catheter insertion, arterial and venous puncture, cutdown and needle puncture). The use of rigid catheters, intramuscular injections and non-essential handling of the patient should be avoided during treatment with METALYSE.

Should serious bleeding occur, in particular cerebral haemorrhage, any concomitant heparin administration should be terminated immediately. Administration of protamine should be considered if heparin has been administered within 4 hours before the onset of bleeding. In the few patients who fail to respond to these conservative measures, judicious use of transfusion products may be indicated. Transfusion of cryoprecipitate, fresh frozen plasma, and platelets should be considered with clinical and laboratory reassessment after each administration. A target fibrinogen level of 1 g/L is desirable with cryoprecipitate infusion. Antifibrinolytic agents should also be considered.

The use of METALYSE therapy has to be carefully evaluated on order to balance the potential risks with anticipated benefits under the following conditions:
- Systolic blood pressure > 160 mm Hg.
- Cerebrovascular disease.
- Recent gastrointestinal or genitourinary bleedings (within the past 10 days).
- Any known recent (within the past 2 days) intramuscular injection.
- Advanced age, i.e. over 75 years.
- Low body weight < 60 kg.
- Patients receiving oral anticoagulants treatment: The use of METALYSE may be considered when appropriate test(s) of anticoagulant activity for the product(s) concerned show no clinically relevant activity.

**Arrhythmias**
Coronary thrombolysis may result in arrhythmias associated with reperfusion. Reperfusion arrhythmias may lead to cardiac arrest, can be life threatening and may require the use of conventional antiarrhythmic therapies.

**Glyco-Protein IIb/IIIa antagonists**
The concomitant use of GPIIb/IIIa antagonists increases the risk of bleeding.

**Thrombo-embolism**
The use of METALYSE can increase the risk of thrombo-embolic events in patients with left heart thrombus, e.g., mitral stenosis or atrial fibrillation.

**Hypersensitivity**
No antibody formation to the tenecteplase molecule has been observed after treatment. However, there is no experience with re-administration of METALYSE. Anaphylactoid reactions associated with the administration of METALYSE are rare and can be caused by hypersensitivity to the active substance tenecteplase, gentamicin (a trace residue from the manufacturing process) or to any of the excipients. If an anaphylactoid reaction occurs, the injection should be discontinued and appropriate treatment should be initiated.

**Use in Pregnancy**
There is a limited amount of data from the use of METALYSE in pregnant women.

Nonclinical studies performed with tenecteplase have shown bleeding with secondary mortality of dams due to the known pharmacological activity of the drug and in a few cases abortion and resorption of the foetus occurred (effects only have been observed with repeated dose
administration). Tenecteplase is not considered to be teratogenic (see Further Information - Toxicology).

The benefit of treatment must be evaluated against the potential risks in case of myocardial infarction during pregnancy.

**Use in Lactation**
It is not known if tenecteplase is excreted into breast milk.

**Fertility**
Clinical data as well as nonclinical studies on fertility are not available for tenecteplase.

**Effects on Ability to Drive and Use Machines**
Not applicable.

**Adverse Effects**
As with other thrombolytic agents, haemorrhage is the most common undesirable effect associated with the use of METALYSE. Haemorrhage at any site or body cavity can occur and may result in life-threatening situations, permanent disability or death.

The type of haemorrhage associated with thrombolytic therapy can be divided into two broad categories:
- superficial bleeding, normally from injection sites
- internal bleeding at any site or body cavity.

With intracranial haemorrhage neurological symptoms such as somnolence, aphasia, hemiparesis, convulsion may be associated.

**Immune system disorders**
anaphylactoid reaction including
- rash
- urticaria
- bronchospasm
- laryngeal oedema

**Nervous system disorders**
intracranial haemorrhage such as
- cerebral haemorrhage
- cerebral haematoma
- haemorrhagic stroke
- haemorrhagic transformation of stroke
- intracranial haematoma
- subarachnoid haemorrhage

**Eye disorders**
eye haemorrhage

**Cardiac disorders**
reperfusion arrhythmias such as
- asystole
- accelerated idioventricular arrhythmia
- arrhythmia
- extrasystoles
- atrial fibrillation
- atrioventricular block first degree - atrioventricular block complete
- bradycardia
- tachycardia
ventricular arrhythmia
ventricular fibrillation
ventricular tachycardia

occur in close temporal relationship to treatment with METALYSE.

Reperfusion arrhythmias may lead to cardiac arrest, can be life threatening and may require the use of conventional antiarrhythmic therapies.

pericardial haemorrhage

Vascular disorders
haemorrhage
embolism

Respiratory, thoracic and mediastinal disorders
epistaxis
pulmonary haemorrhage

Gastrointestinal disorders
gastrointestinal haemorrhage such as
- gastric haemorrhage
- gastric ulcer haemorrhage
- rectal haemorrhage
- haematemesis
- melaena
- mouth haemorrhage

nausea
vomiting
retroperitoneal haemorrhage such as
- retroperitoneal haematoma

Skin and subcutaneous tissue disorders
ecchymosis

Renal and urinary disorders
urogenital haemorrhage such as
- haematuria
- haemorrhage urinary tract

General disorders and administration site conditions
injection site haemorrhage
puncture site haemorrhage

Investigations
blood pressure decreased
body temperature increased

Injury, poisoning and procedural complications
fat embolism, which may lead to corresponding consequences in the organs concerned

Surgical and medical procedures
transfusion
Interactions
No formal interaction studies with METALYSE and medicinal products commonly administered in patients with AMI have been performed. However, the analysis of data from more than 12,000 patients treated during phase I, II and III did not reveal any clinically relevant interactions with medicinal products commonly used in patients with AMI and concomitantly used with METALYSE.

Medicinal products that affect coagulation or those that alter platelet function may increase the risk of bleeding prior to, during or after METALYSE therapy.

Overdose
In the event of an overdose there may be increased risk of bleeding. In case of severe prolonged bleeding, substitution therapy may be considered (plasma, platelets).

Pharmaceutical Precautions
Store below 30°C. Protect from Light

The reconstituted solution may be kept for 24 hours at 2-8°C and 8 hours at 30°C. From a microbial point of view the product should be used immediately after reconstitution. If not used immediately, in-use storage times and conditions prior to use are the responsibility of the user and would normally not be longer than 24 hours at 2 to 8°C or 8 hours at 30°C.

Medicine Classification
Prescription Medicine

Package Quantities
METALYSE 40 mg (8,000U) and 1 prefilled syringe with 8 ml water for injection. (Not marketed)
METALYSE 50 mg (10,000U) and 1 prefilled syringe with 10 ml water for injection.

Further Information
METALYSE is a registered trademark.

Excipients
L-Arginine, Phosphoric Acid, Polysorbate 20. Metalyse may contain a trace residue of gentamicin from the manufacturing process

Incompatibilities
METALYSE is incompatible with dextrose infusion solutions. No other medicinal product should be added to the injection solution or infusion line.

Instructions for use and handling, and disposal
METALYSE should be reconstituted by adding the complete volume of Water For Injection (WFI) from the pre-filled syringe to the vial containing the powder for injection.

1. Ensure that the appropriate vial size is chosen according to the body weight of the patient (see Dosage and Administration).
2. Check that the cap of the vial is still intact.
3. Remove the flip-off cap from the vial.
4. Remove the tip-cap from the syringe. Then immediately screw the pre-filled syringe on the vial adapter and penetrate the vial stopper in the middle with the spike of the vial adapter.
5. Add the water for injections into the vial by pushing the syringe plunger down slowly to avoid foaming.
6. Reconstitute by swirling gently.
7. The reconstituted preparation results in a colourless to pale yellow, transparent solution. Only clear solution without particles should be used.
8. Directly before the solution is administered, invert the vial with the syringe still attached, so that the syringe is below the vial.
9. Transfer the appropriate volume of reconstituted solution of METALYSE into the syringe, based on the patient’s weight.
10. Disconnect the syringe from the vial adapter.
11. METALYSE should be administered to the patient, intravenously over 5 to 10 seconds. It should not be administered in a line containing dextrose.
12. Any unused solution should be discarded.
13. Alternatively the reconstitution can be performed with the included needle.

Alternatively the reconstitution can be performed with the included needle.

**Toxicology**

Intravenous single dose administration in rats, rabbits and dogs resulted only in dose-dependent and reversible alterations of the coagulation parameters with local haemorrhage at the injection site, which was regarded as a consequence of the pharmacodynamic effect of tenecteplase. Multiple-dose toxicity studies in rats and dogs confirmed these above-mentioned observations, but the study duration was limited to two weeks by antibody formation to the human protein tenecteplase, which resulted in anaphylaxis.

Safety pharmacology data in cynomolgus monkeys revealed reduction of blood pressure followed by transient changes of ECG but these occurred at exposures that were considerably higher than the clinical exposure.

With regard to the indication and the single dose administration in humans, reproductive toxicity testing was confined to the rabbit, as a sensitive species. Tenecteplase induced no teratogenicity. Repeated dose administration resulted in bleeding with secondary mortality of dams. In a few cases abortion and resorption of the foetus occurred. Effects were not seen after single dose administration of tenecteplase.

Mutagenicity and carcinogenicity are not expected for this class of recombinant proteins and genotoxicity and carcinogenicity testing were not necessary.

No local irritation of the blood vessel was observed after intravenous, intra-arterial or paravenous administration of the final formulation of tenecteplase.
