New Zealand Data Sheet
SANDOSTATIN® LAR®
Octreotide Acetate
10 mg, 20mg and 30mg
Powder and Solvent for Suspension for Injection.

Description and composition
Pharmaceutical form
Powder for injection and diluent.
Powder: white to off-white powder.
Diluent: clear, colourless solution.
Sandostatin® LAR® is a long-acting depot injection form of octreotide. Powder (microspheres for suspension for injection) to be suspended in a vehicle immediately prior to i.m. injection. Sandostatin LAR suspension contains less than 1 mmol (23 mg) of sodium per dose, i.e. essentially ‘sodium-free’.

Active
The active substance is octreotide free peptide. 10 mg, 20 mg or 30 mg nominally 4.15% of fill weight equivalent to 4.65% of octreotide acetate.

Excipients
For a full list of excipients, see List of excipients.

Indications
Treatment of patients with acromegaly:
• in whom surgery or radiotherapy is inappropriate or ineffective, or in the interim period until radiotherapy becomes fully effective.

Treatment of patients with symptoms associated with functional gastro-entero-pancreatic endocrine tumours:
• Carcinoid tumours with features of the carcinoid syndrome.
• VIPomas.
• Glucagonomas.
• Gastrinomas/Zollinger-Ellison syndrome.
• Insulinomas, for pre-operative control of hypoglycaemia and for maintenance therapy.
• GRFomas.

Treatment of patients with progression of well-differentiated, advanced neuroendocrine tumours of the midgut or suspected midgut origin.

Dosage and administration
Sandostatin LAR may only be administered by deep intragluteal injection. The site of repeat intragluteal injections should be alternated between the left and right gluteal muscle (see Instructions for use/handling).

Dosage
General target population
Acromegaly
It is recommended to start treatment with the administration of 20 mg Sandostatin LAR at 4-week intervals for 3 months. Patients on treatment with s.c. Sandostatin can start treatment with Sandostatin LAR the day after the last dose of s.c. Sandostatin. Subsequent dosage adjustment should be based on serum growth hormone (GH) and insulin-like growth factor 1/somatomedin C (IGF 1) concentrations and clinical symptoms.
For patients in whom, within this 3 month period, clinical symptoms and biochemical parameters (GH; IGF 1) are not fully controlled (GH concentrations still above 2.5 microgram/L), the dose may be increased to 30 mg every 4 weeks.

For patients whose GH concentrations are consistently below 1 microgram/L, whose IGF 1 serum concentrations normalised, and in whom most reversible signs/symptoms of acromegaly have disappeared after 3 months of treatment with 20 mg, 10 mg Sandostatin LAR may be administered every 4 weeks. However, particularly in this group of patients, it is recommended to closely monitor adequate control of serum GH and IGF 1 concentrations, and clinical signs/symptoms at this low dose of Sandostatin LAR.

For patients on a stable dose of Sandostatin LAR, assessment of GH and IGF 1 should be made every 6 months.

**Gastro-entero-pancreatic endocrine tumours**

**Treatment of patients with symptoms associated with functional gastro-entero-pancreatic neuroendocrine tumours**

It is recommended to start treatment with the administration of 20 mg Sandostatin LAR at 4-week intervals. Patients on treatment with s.c. Sandostatin should continue at the previously effective dosage for 2 weeks after the first injection of Sandostatin LAR.

For patients in whom symptoms and biological markers are well controlled after 3 months of treatment, the dose may be reduced to 10 mg Sandostatin LAR every 4 weeks.

For patients in whom symptoms are only partially controlled after 3 months of treatment, the dose may be increased to 30 mg Sandostatin LAR every 4 weeks.

For days when symptoms associated with gastro-entero-pancreatic tumours may increase during treatment with Sandostatin LAR, additional administration of s.c. Sandostatin is recommended at the dose used prior to the Sandostatin LAR treatment. This may occur mainly in the first 2 months of treatment until therapeutic concentrations of octreotide are reached.

**Treatment of patients with advanced Neuroendocrine Tumours of the midgut or of suspected midgut origin:**

The recommended dose of Sandostatin LAR is 30 mg administered every 4 weeks (see Pharmacodynamic properties). Treatment with Sandostatin LAR for tumour control should be continued in the absence of tumour progression.

**Special populations**

**Renal impairment**

Impaired renal function did not affect the total exposure (AUC) to octreotide when administered s.c. as Sandostatin. Therefore, no dose adjustment of Sandostatin LAR is necessary.

**Hepatic impairment**

In a study with Sandostatin administered s.c. and i.v. it was shown that the elimination capacity may be reduced in patients with liver cirrhosis, but not in patients with fatty liver disease. Due to the wide therapeutic window of octreotide, no dose adjustment of Sandostatin LAR is necessary in patients with liver cirrhosis.

**Geriatric population**

In a study with Sandostatin administered s.c., no dose adjustment was necessary in subjects ≥ 65 years of age. Therefore, no dose adjustment is necessary in this group of patients with Sandostatin LAR.
Paediatric population
There is limited experience with the use of Sandostatin LAR in children.

Contraindications
Known hypersensitivity to octreotide or to any of the excipients, (see List of excipients).

Warnings and precautions

General
As GH-secreting pituitary tumours may sometimes expand, causing serious complications (e.g. visual field defects), it is essential that all patients be carefully monitored. If evidence of tumour expansion appears, alternative procedures are advisable.

The therapeutic benefits of a reduction in growth hormone (GH) levels and normalization of insulin-like growth factor 1 (IGF-1) concentration in female acromegalic patients could potentially restore fertility. Female patients of childbearing potential should be advised to use adequate contraception if necessary during treatment with octreotide (see also Pregnancy, breast-feeding and fertility).

Thyroid function should be monitored in patients receiving prolonged treatment with octreotide.

Cardiovascular related events
Cases of bradycardia have been reported (frequency: common). Dose adjustments of drugs such as beta-blockers, calcium channel blockers, or agents to control fluid and electrolyte balance, may be necessary.

Gallbladder and related events
Development of gallstones has been reported in 15 to 30% of long-term recipients of s.c. Sandostatin. The prevalence in the general population (aged 40 to 60 years) is about 5 to 20%. Long-term exposure to Sandostatin LAR of patients with acromegaly or gastro-entero-pancreatic tumours suggests that treatment with Sandostatin LAR does not increase the incidence of gallstone formation, compared with s.c. treatment. Ultrasonic examination of the gallbladder before and at about 6 monthly intervals during Sandostatin LAR therapy is however recommended. If gallstones do occur, they are usually asymptomatic; symptomatic stones should be treated either by dissolution therapy with bile acids or by surgery.

Glucose metabolism
Because of its inhibitory action on growth hormone, glucagon and insulin release, Sandostatin LAR may affect glucose regulation. Post-prandial glucose tolerance may be impaired. As reported for patients treated with s.c. Sandostatin, in some instances, a state of persistent hyperglycaemia may be induced as a result of chronic administration. Hypoglycaemia has also been reported.

In patients with concomitant Type I diabetes mellitus, Sandostatin LAR is likely to affect glucose regulation, and insulin requirements may be reduced. In non-diabetics and type II diabetics with partially intact insulin reserves, Sandostatin s.c. administration may result in increases in post-prandial glycaemia. It is therefore recommended to monitor glucose tolerance and antidiabetic treatment.

In patients with insulinomas, octreotide, because of its greater relative potency in inhibiting the secretion of GH and glucagon than that of insulin, and because of the shorter duration of its inhibitory action on insulin, may increase the depth and prolong the duration of hypoglycaemia. These patients should be closely monitored.

Nutrition
Octreotide may alter absorption of dietary fats in some patients.
Depressed vitamin B₁₂ levels and abnormal Schilling’s tests have been observed in some patients receiving octreotide therapy. Monitoring of vitamin B₁₂ levels is recommended during therapy with Sandostatin LAR in patients who have a history of vitamin B₁₂ deprivation.

**Interactions**
Dose adjustment of medicinal products such as beta blockers, calcium channel blockers, or agents to control fluid and electrolyte balance may be necessary when Sandostatin LAR is administered concomitantly (see section Warnings and precautions).

Dose adjustments of insulin and antidiabetic medicinal products may be required when Sandostatin LAR is administered concomitantly (see section Warnings and precautions).

Octreotide has been found to reduce the intestinal absorption of cyclosporin and to delay that of cimetidine. Concomitant administration of octreotide and bromocriptine increases the bioavailability of bromocriptine.

Limited published data indicate that somatostatin analogs might decrease the metabolic clearance of compounds known to be metabolized by cytochrome P₄₅₀ enzymes, which may be due to the suppression of growth hormone. Since it cannot be excluded that octreotide may have this effect, other drugs mainly metabolized by CYP3A4 and which have a low therapeutic index (e.g. quinidine, terfenadine) should therefore be used with caution.

**Pregnancy, breast-feeding and fertility**

**Pregnancy**
There are no adequate and well-controlled studies in pregnant women. In the post-marketing experience, data on a limited number of exposed pregnancies have been reported in patients with acromegaly, however, in half of the cases the pregnancy outcomes are unknown. Most women were exposed to octreotide during the first trimester of pregnancy at doses ranging from 100 to 300 micrograms/day of Sandostatin s.c. or 20 to 30 mg/month of Sandostatin LAR. In approximately two-thirds of the cases with known outcome, the women elected to continue octreotide therapy during their pregnancies. In most of the cases with known outcome, normal newborns were reported but also several spontaneous abortions during the first trimester, and a few induced abortions.

There were no cases of congenital anomalies or malformations due to octreotide usage in the cases that reported pregnancy outcomes.

Studies with Sandostatin in laboratory animals have not shown reproductive toxicological effects of octreotide. A transient growth retardation of offspring was observed in rats, possibly consequent upon the specific endocrine profile of the species tested (see section Non-clinical safety data).

Sandostatin should only be prescribed to pregnant women under compelling circumstances.

**Breast-feeding**
It is unknown whether octreotide is excreted in human breast milk. Animal studies have shown excretion of octreotide in breast milk. Patients should not breast-feed during Sandostatin treatment.

**Fertility**
It is not known whether octreotide has an effect on human fertility. Octreotide did not impair fertility in male and female rats at doses of up to 1 mg/kg body weight per day. (see section Non-clinical safety data).
Effects on ability to drive and use machines
No data exist on the effects of Sandostatin LAR on the ability to drive and use machines.

Adverse drug reactions

Summary of the safety profile
The most frequent adverse reactions reported during octreotide therapy include gastrointestinal disorders, nervous system disorders, hepatobiliary disorders, and metabolism and nutritional disorders.
The most commonly reported adverse reactions in clinical trials with octreotide administration were diarrhoea, abdominal pain, nausea, flatulence headache, cholelithiasis, hyperglycaemia and constipation. Other commonly reported adverse reactions were dizziness, localized pain, biliary sludge, thyroid dysfunction (e.g., decreased thyroid stimulating hormone [TSH], decreased Total T4, and decreased Free T4), loose stools, impaired glucose tolerance, vomiting, asthenia, and hypoglycaemia.
In rare instances, gastrointestinal side effects may resemble acute intestinal obstruction, with progressive abdominal distension, severe epigastric pain, abdominal tenderness and guarding. Although measured faecal fat excretion may increase, there is no evidence to date that long-term treatment with octreotide has led to nutritional deficiency due to malabsorption.
In very rare instances, acute pancreatitis has been reported within the first hours or days of Sandostatin s.c. treatment and resolved on withdrawal of the drug. In addition, cholelithiasis-induced pancreatitis has been reported for patients on long-term Sandostatin s.c. treatment. In both acromegalic and carcinoid syndrome patients, ECG changes were observed such as QT prolongation, axis shifts, early repolarisation, low voltage, R/S transition, early R wave progression, and non-specific ST-T wave changes. The relationship of these events to octreotide acetate is not established because many of these patients have underlying cardiac diseases (see Special warnings and precautions for use).
The following adverse drug reactions, listed in Table 1, have been accumulated from clinical studies with octreotide:

Adverse drug reactions from clinical trials (Table-1) are listed by MedDRA system organ class. Within each system organ class, the adverse drug reactions are ranked by frequency, with the most frequent reactions first. Within each frequency grouping, adverse drug reactions are presented in order of decreasing seriousness. In addition, the corresponding frequency category for each adverse drug reaction is based on the following convention (CIOMS III):
very common (≥1/10); common (≥1/100 to <1/10); uncommon (≥1/1,000 to <1/100); rare (≥1/10,000 to <1/1,000); very rare (<1/10,000).

**Overdosage**

A limited number of accidental overdoses of Sandostatin LAR have been reported. The doses ranged from 100 mg to 163 mg/month of Sandostatin LAR. The only adverse event reported was hot flushes.

Cancer patients receiving doses of Sandostatin LAR up to 60 mg/month and up to 90 mg/2 weeks have been reported. These doses were in general well tolerated; however, the following adverse events have been reported: frequent urination, fatigue, depression, anxiety, and lack of concentration.

The management of overdosage is symptomatic.

**Clinical Pharmacology**

Pharmacotherapeutic group: anti-growth hormone. ATC code H01CB02.

**Mechanism of Action (MOA)**

Octreotide is a synthetic octapeptide derivative of naturally occurring somatostatin with similar pharmacological effects, but with a considerably prolonged duration of action. It inhibits pathologically increased secretion of growth hormone (GH) and of peptides and serotonin produced within the gastro-entero-pancreatic (GEP) endocrine system.
In *animals*, octreotide is a more potent inhibitor of GH, glucagon and insulin release than somatostatin, with greater selectivity for GH and glucagon suppression. In *healthy subjects* octreotide, like somatostatin, has been shown to inhibit
- release of GH stimulated by arginine, exercise and insulin-induced hypoglycaemia,
- post-prandial release of insulin, glucagon, gastrin, other peptides of the GEP system, and arginine-stimulated release of insulin and glucagon,
- thyrotropin-releasing hormone (TRH)-stimulated release of thyroid-stimulating hormone (TSH).

**Pharmacodynamics (PD)**

Unlike somatostatin, octreotide inhibits GH preferentially over insulin and its administration is not followed by rebound hypersecretion of hormones (i.e. GH in patients with acromegaly). In *patients with acromegaly*, Sandostatin LAR, a galenical formulation of octreotide suitable for repeated administration at intervals of 4 weeks, delivers consistent and therapeutic octreotide serum concentrations thus consistently lowering GH and normalising IGF 1 serum concentrations in the majority of patients. In most patients, Sandostatin LAR markedly reduces the clinical symptoms of the disease, such as headache, perspiration, paraesthesia, fatigue, osteoarthralgia and carpal tunnel syndrome. In individual patients with GH-secreting pituitary adenoma, Sandostatin LAR was reported to lead to shrinkage of the tumour mass. For *patients with functional tumours of the gastro-entero-pancreatic endocrine system*, treatment with Sandostatin LAR provides continuous control of symptoms related to the underlying disease. The effect of octreotide in different types of gastro-entero-pancreatic tumours are as follows:

**Carcinoid tumours:**

Administration of octreotide may result in improvement of symptoms, particularly of flushing and diarrhoea. In many cases, this is accompanied by a fall in plasma serotonin and reduced urinary excretion of 5 hydroxyindole acetic acid.

**VIPomas:**

The biochemical characteristic of these tumours is overproduction of vasoactive intestinal peptide (VIP). In most cases, administration of octreotide results in alleviation of the severe secretory diarrhoea typical of the condition, with consequent improvement in quality of life. This is accompanied by an improvement in associated electrolyte abnormalities, e.g. hypokalaemia, enabling enteral and parenteral fluid and electrolyte supplementation to be withdrawn. In some patients, computer tomography scanning suggests a slowing or arrest of progression of the tumour, or even tumour shrinkage, particularly of hepatic metastases. Clinical improvement is usually accompanied by a reduction in plasma VIP levels, which may fall into the normal reference range.

**Glucagonomas:**

Administration of octreotide results in most cases in substantial improvement of the necrolytic migratory rash which is characteristic of the condition. The effect of octreotide on the state of mild diabetes mellitus which frequently occurs is not marked and, in general, does not result in a reduction of requirements for insulin or oral hypoglycaemic agents. Octreotide produces improvement of diarrhoea, and hence weight gain, in those patients affected. Although administration of octreotide often leads to an immediate reduction in plasma glucagon levels, this decrease is generally not maintained over a prolonged period of administration, despite continued symptomatic improvement.
**Gastrinomas/Zollinger-Ellison syndrome:**
Although therapy with proton pump inhibitors or H2-receptor blocking agents controls the recurrent peptic ulceration which results from chronic gastrin-stimulated hypersecretion of gastric acid, such control may be incomplete. Diarrhoea may also be a prominent symptom not alleviated in all patients by this therapy. Octreotide alone or in conjunction with proton pump inhibitors or H2-receptor antagonists may reduce gastric acid hypersecretion and improve symptoms, including diarrhoea. Other symptoms possibly due to peptide production by the tumour, e.g. flushing, may also be relieved. Plasma gastrin levels fall in some patients.

**Insulinomas:**
Administration of octreotide produces a fall in circulating immunoreactive insulin. In patients with operable tumours, octreotide may help to restore and maintain normoglycaemia pre-operatively. In patients with inoperative benign or malignant tumours, glycaemic control may be improved even without concomitant sustained reduction in circulating insulin levels.

**GRFomas:**
These rare tumours are characterised by production of GH releasing factor (GRF) alone or in conjunction with other active peptides. Octreotide produces improvement in the features and symptoms of the resulting acromegaly. This is probably due to inhibition of GRF and GH secretion, and a reduction in pituitary enlargement may follow.

**Clinical studies**

**Acromegaly**
Two dose finding studies (SMSC 201-E-01 and SMSC 202-E-00) were initially carried out with Sandostatin LAR in acromegalic patients. These studies were prospective single dose, double-blind, randomized, multi-centre studies designed to assess the following doses of Sandostatin LAR injected intramuscularly: 10, 20 and the 30 mg.

Patients who showed GH suppression on t.i.d. Sandostatin s.c. pre-treatment were selected for these studies. Out of the 93 patients included, 78 were "responders" (mean 12-hour GH serum concentrations below 5 µg/L during pre-treatment with Sandostatin s.c.) and 15 patients were "partial responders" to Sandostatin s.c. (GH mean concentrations suppressed to approximately 50% of pre-treatment levels but not to below 5 µg/L).

The primary efficacy parameter was the mean 12-hour GH serum concentrations. The results of the double-blind studies SMSC 201-E-01 and SMSC 202-E-00 showed that the 20 and 30 mg doses of Sandostatin LAR are able to suppress GH levels below 5µg/L from day 14 until day 42. The i.m. injection was well tolerated locally and the adverse events analysis reflected the known gastro-intestinal reactions to octreotide.

To document the long-term tolerability, safety and efficacy of Sandostatin LAR in acromegalic patients, three prospective open-label extensions for each of the two double-blind studies were completed (SMSC 201-E-02/-03/-04 and SMSC 202-E-01/-02/-03).

All patients that had participated to studies SMSC 201-E-01 and SMSC 202-E-00 and had well tolerated the study drug were offered to continue treatment with additional injections of Sandostatin LAR in the open label extension studies. A total of 101 patients entered these studies and 87 completed all extensions, thus receiving 28 injections of Sandostatin LAR.

Investigators were allowed to titrate patients to their optimal therapeutic response (using 10, 20, 30 or exceptionally 40 mg doses). An interval of 28 days between injections was
considered optimal for providing consistent steady-state concentrations of octreotide, based on pharmacokinetic simulation of single dose profiles and considering the linearity of pharmacokinetics of octreotide. The primary efficacy endpoint in the extension studies was the 8-hours GH serum concentrations.

These extension studies demonstrated that long-term treatment of acromegalic patients with Sandostatin LAR administered at doses of 10-30 mg i.m. in patients known to be responsive to Sandostatin s.c. results in a sustained suppression of mean 8-hour GH levels throughout the dosing interval. These effects were accompanied by a marked reduction in IGF-I concentrations and a persistent regression of the symptoms of acromegaly.

Long-term systemic tolerability of Sandostatin LAR was good, the pattern, severity and duration of adverse events was similar to those historically reported for the s.c. treatment with Sandostatin and for short-term treatment with Sandostatin LAR.

**GEP tumours**

The clinical trial program for Sandostatin LAR in GEP tumors consisted of one controlled clinical study (SMSE 351) which was carried out in patients with malignant carcinoid syndrome symptomatically controlled by Sandostatin s.c..

Study SMSE351 was a randomized, double-blind, multicenter prospective study of efficacy, safety and tolerability of multiple dose levels of Sandostatin LAR (10, 20 and 30 mg doses) administered at 4-week intervals versus open-label subcutaneous Sandostatin. Ninety-three patients were enrolled and 80 completed the study.

Assessment of treatment success, partial treatment success or treatment failure was based on the degree and duration of suppression of carcinoid symptoms as indicated by the need for rescue therapy with Sandostatin in patients randomized to one of the Sandostatin LAR groups, or by the need for an increase in dosage in patients randomized to the Sandostatin group, at the end of Week 20 and Week 24.

A level of efficacy comparable to that achieved with Sandostatin s.c. was observed with Sandostatin LAR after the 5th and 6th injections at Weeks 20 and 24 respectively, and at endpoint (see Table 3).

Success = no need for rescue Sandostatin s.c. or increased s.c dosage
Part. Success = need for rescue Sandostatin s.c. or increased s.c dosage on no more than 2 occasions during the preceding 4 weeks for a total of 5 days or less.

Endpoint = last not missing post-baseline evaluation

The data recorded in Study SMSE 351 showed that Sandostatin LAR is as effective and as well tolerated as Sandostatin s.c. injections in the treatment of patients with carcinoid symptoms.

**Advanced Neuroendocrine Tumours of the midgut or unknown primary tumour location:**

An interim analysis of Phase III, randomised, double blind, placebo-controlled study (PROMID) demonstrated that Sandostatin LAR prolongs TTP in patients with advanced, well-differentiated Neuroendocrine Tumours of the midgut as compared to placebo, across all 3 efficacy analysed populations.

No conclusions could be drawn from the PROMID study regarding the secondary endpoint overall survival, as the median overall survival was not reached at the time of interim analysis in the Sandostatin LAR group.

85 patients were randomized to receive Sandostatin LAR 30 mg every 4 weeks (n = 42) or placebo (n = 43) for 18 months, or until tumour progression or death.

Main inclusion criteria were: treatment naïve; histologically confirmed; locally inoperable or metastatic well-differentiated; functionally active or inactive neuroendocrine tumours/carcinomas; with primary tumour located in the midgut or unknown origin believed to be of midgut origin if a primary within the pancreas, chest, or elsewhere was excluded.

The primary endpoint was time to tumour progression or tumour-related death (TTP).

In the intent-to-treat analysis population (ITT) (all randomized patients), 26 and 41 progressions or tumour-related deaths were seen in the Sandostatin LAR and placebo groups, respectively (HR = 0.32; 95% CI, 0.19 to 0.55; p-value =0.000015).

In the conservative ITT (cITT) analysis population in which 3 patients were censored at randomization, 26 and 40 progressions or tumour-related deaths were observed in the Sandostatin LAR and placebo groups, respectively (HR = 0.34; 95% CI, 0.20 to 0.59; p-value =0.000072; Figure 1). Median time to tumour progression was 14.3 months (95% CI, 11.0 to 28.8 months) in the Sandostatin LAR group and 6.0 months (95% CI, 3.7 to 9.4 months) in the placebo group.

In the Per-protocol analysis population (PP) in which additional patients were censored at end study therapy, tumour progression or tumour-related death was observed in 19 and 38 Sandostatin LAR and placebo recipients, respectively (HR = 0.24; 95% CI, 0.13 to 0.45; p-value =0.000036).

NR=not reported; HR=hazard ratio; TTP=time to tumour progression; ITT=intention to treat; cITT=conservative ITT; PP=per protocol

*Logrank test stratified by functional activity

Subgroup analyses on the per-protocol analysis population demonstrated that treatment effect was similar in patients with functionality active (HR=0.23; 95% CI, 0.09 to 0.57), or inactive tumours (HR=0.25; 95% CI, 0.10 to 0.59).

After 6 months of treatment, stable disease was observed in 66% of patients in the Sandostatin LAR group and 37% of patients in the placebo group.

Both treatment groups had comparable levels of global QoL at random assignment and after 6 months of follow up.
Based on the significant benefit of Sandostatin LAR observed in this pre-planned interim analysis the recruitment was stopped after over half (52%) of its intended participants were enrolled (85/162).

In this study, there were limitations in the estimation of the true magnitude of time to tumor progression and disease stabilisation with Sandostatin LAR. Documented progressive disease was not a requirement for study entry and there was a significant imbalance between the groups in time since diagnosis which was a median 7.5 months in the Sandostatin LAR group and 3.3 months in the placebo group (p=0.01). As the treatment effect was relatively large after analysis of tumour progression or tumour related death in the analysed populations, these factors are not likely to affect the significance of the result.

The safety of Sandostatin LAR in this trial was consistent with its established safety profile.

**Pharmacokinetics (PK)**

After single i.m. injections of Sandostatin LAR, the serum octreotide concentration reaches a transient initial peak within 1 hour after administration, followed by a progressive decrease to a low undetectable octreotide level within 24 hours. After this initial peak on day 1, octreotide remains at sub-therapeutic levels in the majority of the patients for the following 7 days. Thereafter, octreotide concentrations increase again, and reach plateau concentrations around day 14 and remain relatively constant during the following 3 to 4 weeks. The peak level during day 1 is lower than levels during the plateau phase and no more than 0.5% of the total drug release occurs during day 1. After about day 42, the octreotide concentration decreases slowly, concomitant with the terminal degradation phase of the polymer matrix of the dosage form.

In patients with acromegaly, plateau octreotide concentrations after single doses of 10 mg, 20 mg and 30 mg Sandostatin LAR amount to 358 ng/L, 926 ng/L, and 1,710 ng/L, respectively. Steady-state octreotide serum concentrations, reached after 3 injections at 4 week intervals, are higher by a factor of approximately 1.6 to 1.8 and amount to 1,557 ng/L and 2,384 ng/L after multiple injections of 20 mg and 30 mg Sandostatin LAR, respectively.

In patients with carcinoid tumours, the mean (and median) steady-state serum concentrations of octreotide after multiple injections of 10 mg, 20 mg and 30 mg of Sandostatin LAR given at 4 week intervals also increased linearly with dose and were 1,231 (894) ng/L, 2,620 (2,270) ng/L and 3,928 (3,010) ng/L, respectively.

No accumulation of octreotide beyond that expected from overlapping release profiles occurred over a duration of up to 28 monthly injections of Sandostatin LAR. The pharmacokinetic profile of octreotide after injection of Sandostatin LAR reflects the release profile from the polymer matrix and its biodegradation. Once released into the systemic circulation, octreotide distributes according to its known pharmacokinetic properties, as described for s.c. administration. The volume of distribution of octreotide at steady-state is 0.27 L/kg and the total body clearance is 160 mL/min. Plasma protein binding amounts to 65% and essentially no drug is bound to blood cells.

**Non-clinical safety**

**Repeat dose toxicity**

In two repeat dose studies performed in rats by i.m. injection of 2.5 mg Sandostatin LAR in 50 mg microspheres every 4 weeks for 21/24 weeks, no drug-related necropsy findings were observed. The only histopathological findings considered to be of significance were at the
injection site in treated and control animals, where the microspheres had provoked a reversible granulomatous myositis.

**Genotoxicity**
Octreotide and/or its metabolites were devoid of mutagenic potential when investigated *in vitro* in validated bacterial and mammalian cell test systems. In one study an increased frequency of chromosomal changes were observed in V79 Chinese hamster cells, albeit at high and cytotoxic concentrations only. Chromosomal aberrations were however not increased in human lymphocytes incubated with octreotide acetate. *In vivo*, no clastogenic activity was observed in the bone marrow of mice treated with octreotide i.v. (micronucleus test) and no evidence of genotoxicity was obtained in male mice using a DNA repair assay on sperm heads. The microspheres were devoid of mutagenic potential when tested in standard assays for genotoxicity.

**Carcinogenicity/chronic toxicity**
In studies in rats in which s.c. Sandostatin at daily doses up to 1.25 mg/kg body weight were administered, fibrosarcomas were observed, predominantly in a number of male animals, at the s.c. injection site after 52, 104 and 113/116 weeks. Local tumours occurred also in the control rats, however development of these tumours was attributed to disordered fibroplasia produced by sustained irritant effects at the injection sites, enhanced by the acidic lactic acid/mannitol vehicle. This non-specific tissue reaction appeared to be particular to rats. Neoplastic lesions were observed neither in mice receiving daily s.c. injections of Sandostatin at doses up to 2 mg/kg for up to 99 weeks, nor in dogs which were treated with daily s.c. doses of the drug for 52 weeks. The 116 week carcinogenicity study in rats with s.c. Sandostatin also revealed uterine endometrial adenocarcinomas, their incidence reaching statistical significance at the highest s.c. dose level of 1.25 mg/kg per day. The finding was associated with an increased incidence of endometritis, a decreased number of ovarian corpora lutea, a reduction in mammary adenomas and the presence of uterine glandular and luminal dilation, suggesting a state of hormonal imbalance. The available information clearly indicates that the findings of endocrine-mediated tumours in rats are species-specific and are not relevant for the use of the drug in humans.

**Reproduction toxicity**
Reproduction studies have been performed with Sandostatin in rats and rabbits at parenteral doses of up to 1 mg/kg body weight per day. Some retardation of the physiological growth was noted in offspring of rats which was transient and most likely attributable to GH inhibition brought about by excessive pharmacodynamic activity. There was no evidence of teratogenic, embryo/foetal or other reproduction effects due to octreotide. The microspheres were devoid of reproductive toxicological effects when tested in standard studies for reproductive toxicity in rats and rabbits.

**Pharmaceutical information**
**List of excipients**
**Vial**
Poly (DL-lactide-co-glycolide) and mannitol.

**Prefilled syringe**
One *prefilled syringe* (diluent for parenteral use), containing: sodium carboxymethylcellulose, mannitol, water for injection.
**Incompatibilities**
Sandostatin LAR microspheres for injection is to be used as a single dose container, without any dilution with other products. Therefore, no compatibility data with other products have been generated.

**Shelf life**
3 years.

**Special precautions for storage**
Store at 2°C to 8°C (in a refrigerator). Do not freeze. Keep vial in the outer carton in order to protect it from light. Sandostatin LAR can remain below 25°C on the day of injection. However, the suspension must only be prepared immediately prior to i.m. injection. Sandostatin LAR must be kept out of the reach and sight of children.

**Nature and contents of container**
The microspheres are packaged in a 5 mL glass vial, with a Teflon-faced rubber stopper and sealed with an aluminium flip-off seal.
The vehicle is packaged in a pre-filled glass syringe containing 2.5 mL diluent which is closed with two rubber stoppers (a front and a plunger stopper).
Two needles [40 mm (1.5 inch), 19 gauge].

**Special precautions for disposal**
Any unused product or waste material should be disposed of in accordance with local requirements.

**Instructions for use and handling**
Instructions for intramuscular injection of Sandostatin LAR
FOR DEEP INTRAGLUTEAL INJECTION ONLY

Content:

One vial containing Sandostatin LAR
One prefilled syringe containing vehicle solution + two needles

Follow the instructions below carefully to ensure complete saturation of the powder and its uniform suspension before i.m. injection.
Sandostatin LAR suspension must only be prepared immediately before administration.
Sandostatin LAR should only be administered by a trained health professional.

Allow the Sandostatin LAR vial and the vehicle syringe to reach room temperature.
Remove the cap from vial containing Sandostatin LAR. Assure that the powder is settled at the bottom of the vial by lightly tapping the vial.
Remove the cap from the vehicle syringe.  
Attach one of the supplied needles to the vehicle syringe.

Disinfect the rubber stopper of the vial with an alcohol swab.  
Insert the needle through the centre of the rubber stopper of the Sandostatin LAR vial.

Without disturbing the Sandostatin LAR powder, gently inject all the vehicle into the vial by running the vehicle down the inside wall of the vial. Do not inject the vehicle directly into the powder.Withdraw the needle from the vial.

**Do not disturb the vial** until the vehicle has totally wetted the Sandostatin LAR powder (at least 2 to 5 minutes). **Without inverting the vial** check the powder on the walls and bottom of the vial. If dry spots exist, allow undisturbed wetting to continue. At this stage, prepare the patient for injection.

Once complete wetting has occurred, the vial should be moderately swirled for about 30 to 60 seconds until a uniform milky suspension is achieved. **Do not vigorously shake the vial** as this may cause the suspension to flocculate, making it unusable.

Immediately re-insert the needle through the rubber stopper and then, with the bevel down and the vial tipped at approximately 45 degree angle, slowly draw the contents of the vial into the syringe. **Do not invert the vial** when filling the syringe as this may affect the amount withdrawn.  
It is normal for a small amount of suspension to remain on the walls and bottom of the vial. This is a calculated overfill. Immediately change the needle (supplied).
Administration must occur immediately after the suspension has been prepared. Gently invert the syringe as needed to maintain a uniform suspension. Eliminate air from syringe.

Disinfect the injection site with an alcohol swab. Insert needle into right or left gluteus and draw back to ensure that no blood vessel has been penetrated. Inject slowly i.m. by deep intragluteal injection with steady pressure. If the needle blocks, attach a new needle of the same diameter [1.1 mm, 19 gauge].

Sandostatin LAR must be given only by deep intragluteal injection, never i.v. If a blood vessel has been penetrated, attach a new needle and select another injection site.

**Recommendation for the management of patients during Sandostatin LAR treatment with respect to the development of gallstones**

1. Patients should undergo a baseline ultrasound examination of the gallbladder prior to commencing octreotide treatment.
2. Periodic repeat ultrasound examination of the gallbladder should be performed, preferably at about 6-month intervals, throughout Sandostatin LAR treatment.
3. If stones are already present before the start of therapy, the potential benefit of Sandostatin LAR should be assessed against the potential risks associated with the gallstones. There is no evidence at present that Sandostatin LAR adversely affects the course or prognosis of pre-existing gallstones.
4. Management of patients who develop gallstones in association with Sandostatin LAR:
   i. Asymptomatic gallstones
      Sandostatin LAR may be continued, depending on re-assessment of the benefit/risk ratio. Either way, no action is required except to continue monitoring, with increased frequency if this is considered necessary.
   ii. Symptomatic gallstones
      Sandostatin LAR may be either stopped or continued, depending on re-assessment of the benefit/risk ratio. Either way, the gallstones should be treated like any other symptomatic gallstones. Medically, this may include combined bile acid therapy (e.g. chenodeoxycholic acid together with ursodeoxycholic acid [UDCA] or monotherapy with ursodeoxycholic acid (UDCA) associated with ultrasound monitoring until the stones have completely disappeared. For posology and treatment duration, please consult the locally approved prescribing information for CDCA and/or UDCA.
