DATA SHEET

**Fexofenadine**
Fexofenadine Tablets

**Presentation**
Fexofenadine 120 mg Tablets are pink coloured, capsule- shaped film coated tablets imprinted with "F1" in black ink on one side and plain on the other side containing 120 mg fexofenadine hydrochloride.

Fexofenadine 180 mg Tablets are pink coloured, capsule- shaped film coated tablets imprinted with "F2" in black ink on one side and plain on the other side containing 180 mg fexofenadine hydrochloride.

**Uses**
Fexofenadine hydrochloride is the synthetic hydrochloride salt of fexofenadine, the carboxylic acid metabolite of terfenadine (Teldane). It is an orally active non-sedating H₁-receptor antagonist and is effective for the relief of symptoms associated with seasonal allergic rhinitis (sneezing, rhinorrhea, pruritus and lacrimation).

**Actions**
Fexofenadine is the major metabolite of terfenadine in man and is largely responsible for the antihistaminic effect following the administration of terfenadine.

The antihistaminic effects of fexofenadine have been demonstrated in animal systems *in vitro* and *in vivo*. Oral administration of fexofenadine to guinea pigs indicated that fexofenadine antagonised histamine-induced skin wheals in a dose-dependent manner. The antihistaminic effects of fexofenadine and terfenadine were also assessed in the isolated guinea pig ileum *in vitro*. Both drugs antagonised the contractile effects of histamine, however, fexofenadine was found to be a more selective histamine antagonist than terfenadine.

Fexofenadine inhibited antigen induced bronchospasm in sensitised guinea pigs and at high doses inhibited histamine release from peritoneal mast cells of the rat.

In laboratory animals, no anticholinergic or alpha-1-adrenergic receptor blocking effects were observed. Radiolabelled tissue distribution studies in rat indicated that fexofenadine did not cross the blood brain barrier.

Fexofenadine is not associated with significant ECG abnormalities. Studies have shown that fexofenadine does not affect the action potential and ion channel currents (Iₖ, IₐCa, IₐNa) in guinea pig or neonatal rat myocytes. The effect of fexofenadine on blocking a delayed rectifier potassium channel cloned from human heart was 583 times less potent than the same effect with terfenadine.
Doses of fexofenadine, ten times greater than the dose of terfenadine producing prolongation of QTc intervals, do not prolong QTc intervals in anaesthetised rabbits and conscious dogs. An escalating acute-dose study demonstrated antihistaminic activity via skin wheal and flare inhibition at doses ranging from 10 to 800mg, with maximum inhibition reaching a plateau at a dose of 130mg. An escalating repeat-dose study demonstrated increasing skin flare inhibition at twice daily doses ranging from 20 to 690mg. During both acute-dose and repeat-dose studies an antihistaminic effect was observed within one hour, achieving maximum effect within 2-4 hours and lasting a minimum of 12 hours. There is no evidence of tolerance to these effects after 28 days of dosing.

In dose-ranging studies, fexofenadine hydrochloride was shown to relieve the symptoms of seasonal allergic rhinitis, significantly reducing total symptom scores (including scores for nasal congestion, sneezing, rhinorrhea, itchy nose, palate and/or throat, and itchy, watery, red eyes) over a dosage range of 40 to 240mg twice daily.

The 60mg twice daily dose was determined to be the optimal dose as reduction in symptom severity was similar over the 40–240mg dosage range, however, the 60mg dose had a faster onset of action than the 40mg dose. Significant symptom reduction was observed one hour following a single 60mg dose of fexofenadine hydrochloride. Onset of action was similar for doses of 60–240mg.

In controlled clinical studies, fexofenadine hydrochloride 120mg once daily was shown to relieve the symptoms of seasonal allergic rhinitis, significantly reducing total symptom scores (including scores for nasal congestion, sneezing, rhinorrhea, itchy nose, palate and/or throat, and itchy, watery, red eyes.

The incidence of drowsiness in controlled clinical seasonal allergic rhinitis trials was similar when comparing patients treated with fexofenadine hydrochloride (1.3%) and placebo (0.9%). There was no dose-related increase in drowsiness.

The effects of fexofenadine on the QTc interval have been investigated in a variety of studies at doses up to 800mg/day. There were no statistically significant differences in QTc interval between fexofenadine hydrochloride and placebo patients. Similarly, there were no statistically significant differences from placebo of dose-related changes in other ECG parameters as a result of fexofenadine hydrochloride treatment.

Interaction studies involving erythromycin and ketoconazole demonstrated that, although the plasma AUC for fexofenadine increased approximately 2–3 fold, there were no significant effects on ECG, nor were there any effects on the incidence of adverse events. These changes in plasma levels were within the range of plasma levels achieved in adequate and well-controlled clinical trials.

The duration of the clinical studies presented for evaluation was limited to two weeks, however, studies on longer term use are ongoing.
Pharmacokinetics

Fexofenadine hydrochloride is rapidly absorbed following oral administration. $T_{\text{max}}$ occurred approximately 1-3 hours postdose. The mean $C_{\text{max}}$ was approximately 142ng/mL following the administration of a single 60mg dose, approximately 289ng/mL following a single 120mg dose and approximately 494ng/mL following a single 180mg dose.

In 7-12 year old allergic rhinitis patients, cross study comparisons indicated that fexofenadine area under the curve following oral administration of a 60mg dose was 56% greater compared to healthy adult subjects given the same dose. Additionally, fexofenadine clearance in paediatric patients has been determined to be approximately 40% lower than in adults. In view of this a dose of 30mg twice daily in paediatric patients will provide plasma fexofenadine concentration that are comparable to those associated with efficacy in adults. Administration of a 15 mg dose of fexofenadine to paediatric subjects aged 6 to 23 months, and of a 30 mg dose to paediatric subjects 2 to 11 years, produced exposures comparable to those seen with a dosage of 60 mg administered to adults.

The absolute bioavailability following fexofenadine hydrochloride administration is calculated to be 33%. Fexofenadine is 60–75% bound to plasma proteins in healthy subjects. Fexofenadine undergoes negligible metabolism.

Absorption of fexofenadine is not significantly altered by food.

Following a single 60mg oral dose, 80% and 11.5% of total fexofenadine dose was excreted in the faeces and urine respectively. Following multiple dosing, fexofenadine has a mean terminal elimination half-life of 11-16 hours. The major route of elimination is believed to be biliary excretion while up to 10% of the ingested dose is excreted unchanged through the urine.

The single and multiple dose pharmacokinetics of fexofenadine are linear between 20mg and 120mg doses. A dose of 240mg twice daily produced slightly greater than proportional increase (8.8%) in steady state area under the curve.

The pharmacokinetics of fexofenadine in seasonal allergic rhinitis patients are similar to those in healthy subjects. One study indicated that females may be exposed to higher plasma levels than males, however, there was no indication of any difference in safety or efficacy. Elderly patients, patients with hepatic impairment and patients with cardiac disease exposed to fexofenadine by administration of terfenadine showed no statistically significant differences in pharmacokinetic parameters for fexofenadine compared to healthy individuals. Although peak plasma level and half-life were increased 68% and 15% respectively in elderly patients and 54% and 19% respectively in patients with renal disease regardless of disease severity, these levels are within the range of plasma levels shown to be well tolerated in adequate and well controlled safety and efficacy trials.
**Indications**
Relief of symptoms associated with seasonal allergic rhinitis and allergic rhinitis in adults and children from 2 years of age.

Relief of symptoms of urticaria in adults and children from 6 months of age.

**Dosage and Administration**

*Not all dosages listed can be provided by the tablet dosage forms available.*

**Paediatrics**

**Allergic Rhinitis and Seasonal Allergic Rhinitis:**
Children aged 2 to 11 years: 30 mg twice daily, when required.

**Urticaria:**
Children aged 6 to 23 months: 15 mg twice daily, when required.
Children aged 2 to 11 years: 30 mg twice daily, when required.

**Adults and Children aged 12 years or older**

**Allergic Rhinitis:**
60 mg twice daily, when required.

**Seasonal Allergic Rhinitis:**
120 mg or 180 mg once daily, when required.

**Urticaria:**
180 mg once daily, when required.

The efficacy and safety of Telfast has not been established in children under 2 years of age for seasonal allergic rhinitis and under 6 months of age for urticaria.

**Special Risk Groups**

Studies in special risk groups (elderly, renally or hepatically impaired patients) indicate that it is not necessary to adjust the dose of fexofenadine hydrochloride in these patients.

**Contraindications**

Telfast is contraindicated in patients with a known hypersensitivity to fexofenadine or any of its ingredients.

**Warnings and Precautions**

Studies in the elderly, patients with hepatic impairment and patients with cardiac disease exposed to fexofenadine through administration of terfenadine showed no statistically significant differences in pharmacokinetic parameters for fexofenadine when compared to those pharmacokinetic parameters in healthy individuals.
As with most new drugs there is only limited data in the elderly and renally or hepatically impaired patients. Fexofenadine hydrochloride should be administered with care in these special groups.

**Pregnancy and Lactation**

Category B2.

Reproductive toxicity of fexofenadine in animals was assessed through terfenadine exposure. Data from supporting pharmacokinetic studies, showing the extent of fexofenadine exposure, demonstrate that these studies are relevant to the assessment of fexofenadine hydrochloride. No evidence of teratogenicity was observed in animal reproduction studies (rat and rabbit) when terfenadine was given at oral doses of up to 300mg/kg/day throughout organogenesis which corresponds to levels of systemic fexofenadine exposure 4– and 32–fold higher, respectively, than those anticipated in clinical use. No effects on male or female fertility or perinatal or postnatal development were observed in terfenadine animal studies at non-maternally toxic doses.

There are no studies in pregnant women exposed to fexofenadine hydrochloride alone or through the administration of terfenadine. As with other medications, Telfast should be used during pregnancy only if the potential benefit justifies the potential risk to the foetus.

There are no studies of Telfast in lactating women. Telfast is not recommended for nursing women and should only be used if in the physician’s judgement, the potential benefit outweighs the potential risk to the infant. There are no data on the content of human milk after administering fexofenadine hydrochloride. However, when terfenadine was administered to nursing mothers, fexofenadine was found to cross into human breast milk.

Exposure of rats to fexofenadine and terfenadine through the administration of terfenadine at doses of 150 and 300mg/kg/day throughout pregnancy and lactation (corresponding to systemic exposure at levels (AUC) approximately 3– and 6–fold higher than those anticipated in clinical use) caused decreased pup weight gain and survival in offspring. The relative risks of these effects from terfenadine or fexofenadine are unknown. Effects on pups exposed to fexofenadine only during lactation are not known.

**Carcinogenic/Mutagenic Potential**

The carcinogenic potential of fexofenadine was assessed using terfenadine studies with supporting pharmacokinetics studies showing fexofenadine exposure (via plasma AUC values). No evidence of carcinogenicity was observed in rats and mice given terfenadine.

Fexofenadine was found not to be mutagenic in various *in vitro* and *in vivo* mutagenicity tests.

**Effects on Ability to Drive and Use Machines**

The incidence of drowsiness in controlled clinical seasonal allergic rhinitis trials was similar when comparing patients treated with fexofenadine and placebo. There was no dose-related increase in drowsiness.
On the basis of the pharmacodynamic profile and reported adverse events it is unlikely that fexofenadine hydrochloride tablets will produce an effect on the ability to drive or use machines. In objective tests, Telfast has been shown to have no significant effects on central nervous system function. This means that patients may drive or perform tasks that require concentration.

**Adverse Effects**

Telfast is generally well tolerated. In placebo controlled clinical trials involving seasonal allergic rhinitis and chronic idiopathic urticaria the most commonly reported adverse events were headache (>3%), drowsiness, nausea, fatigue and dizziness (1-3%). The incidence of these events observed with fexofenadine hydrochloride was similar to that observed with placebo and no apparent dose trends were revealed in adverse events.

Events that have been reported during controlled clinical trials involving seasonal allergic rhinitis and chronic idiopathic urticaria patients with incidences less than 1% and similar to placebo, and have been reported rarely during post marketing surveillance, include: fatigue, insomnia, nervousness and sleep disorders or paroniria. In rare cases, rash, urticaria, pruritis and hypersensitivity reactions such as angioedema, dyspnoea, chest tightness, flushing and systemic anaphylaxis have been reported.

No notable dose effects on QTc were found.

Adverse events reported in placebo-controlled chronic idiopathic urticaria studies were similar to those reported in placebo-controlled seasonal allergic rhinitis studies. In placebo controlled trials involving paediatric patients (6-11 years of age), adverse events were similar to those observed in trials involving patients 12 years and older, with incidences similar to placebo. In controlled clinical trials involving paediatric patients 6 months to 5 years of age, there were no unexpected adverse events in patients treated with fexofenadine hydrochloride.

**Interactions**

Since fexofenadine does not undergo hepatic biotransformation, it is unlikely to interact with drugs that rely upon hepatic metabolism.

Interaction studies with erythromycin and ketoconazole have shown that although the plasma levels of fexofenadine are increased 2–3 fold, there were no changes to QT interval and there were no changes to the incidence of any adverse events. The concentration of fexofenadine experienced by individuals during the interaction studies are well within the range experienced in acute and chronic dose-tolerance studies. Animal studies have shown that the increase in plasma levels of fexofenadine observed after co-administration of erythromycin or ketoconazole, appears to be due to an increase in gastrointestinal absorption and either a decrease in biliary excretion or gastrointestinal secretion, respectively.

No interaction between fexofenadine and omeprazole was observed. However, the administration of an antacid containing aluminium and magnesium hydroxide gels 15
minutes prior to fexofenadine hydrochloride caused a reduction in bioavailability, most likely due to binding in the gastrointestinal tract. It is advisable to leave 2 hours between administration or fexofenadine hydrochloride and aluminium and magnesium hydroxide containing antacids.

**Overdosage**

Most reports of fexofenadine hydrochloride overdose contain limited information. However, dizziness, drowsiness and dry mouth have been reported. Single doses up to 800mg and doses up to 690mg twice daily for 1 month were studied in healthy subjects without the development of clinically significant adverse events.

Clinical signs of toxicity and effects on body weight or food consumption were not observed in acute toxicity studies in several animal species administered fexofenadine by oral lavage at doses of 2,000mg/kg.

In the case of an overdose, standard measures to remove any unabsorbed drug should be employed. Symptomatic and supportive treatment is recommended. Haemodialysis is not an effective means of removing fexofenadine from plasma.

There has been no reported case of an acute overdose of fexofenadine hydrochloride.

**Pharmaceutical Precautions**

Store below 25°C.

**Medicine Classification**

Pharmacy Only Medicine.

**Package Quantities**

Fexofenadine 120mg - Blister packs of 10 and 30 tablets.
Fexofenadine 180mg - Blister packs of 10 and 30 tablets.
