1. Product Name

Lanzol Relief, 15 mg and 30 mg, capsules.

2. Qualitative and Quantitative Composition

Each capsule contains 15 mg or 30 mg of lansoprazole.

For the full list of excipients, see section 6.1.

3. Pharmaceutical Form

LANZOL RELIEF 15 mg capsules are presented as white to off-white coloured pellets filled in hard gelatin capsules with a green opaque cap and a green opaque body imprinted with ‘MYLAN’ over ‘8015’ on both cap and body with black ink.

LANZOL RELIEF 30 mg capsules are presented as white to off-white coloured pellets filled in hard gelatin capsules with a pink opaque cap and a pink opaque body imprinted with ‘MYLAN’ over ‘8030’ on both cap and body with black ink.

4. Clinical Particulars

4.1 Therapeutic indications

Healing and long-term management of reflux oesophagitis.

Healing and maintenance therapy for patients with duodenal ulcer.

Healing of benign gastric ulcer.

Lansoprazole is also effective in patients with benign peptic lesions that do not respond to H₂-receptor antagonists.

The United States National Institute of Health have recommended that regimens to eradicate *H. pylori* in patients with peptic ulcer disease should contain both anti-secretary agents and anti-microbial agents (to which *H. pylori* has been demonstrated to be sensitive *in vivo*).

In an open, multicentre, comparative study in over 500 patients, 7 days treatment with lansoprazole 30 mg twice daily, in combination with the recommended antibiotics, was safe and efficacious in eradication of *H. Pylori* from patients with duodenal ulcer or gastritis and who tested positive for *H. Pylori*, with *H. Pylori* eradication rates of up to 90%.

4.2 Dose and method of administration
Dose

Reflex oesophagitis
30 mg lansoprazole once daily for 4 weeks. The majority of patients will be healed after the first course. For patients who have not fully healed within this time, a further 4 weeks treatment using the same dosage regimen is indicated. For long-term management, a maintenance dose of 15 mg or 30 mg once daily can be used dependent upon patient response.

Duodenal ulcer
30 mg lansoprazole once daily for 4 weeks. For the prevention of relapse, the recommended maintenance dose is 15 mg once daily.

Gastric ulcer
30 mg lansoprazole once daily for 8 weeks.

Eradication of H. pylori
Eradication of the infection is the single most important therapeutic intervention in patients with H. pylori positive peptic ulcer disease. The following combinations have been shown to be effective when used for 7 days: 30 mg twice daily plus two of the following antibiotics: amoxicillin 1g twice daily, metronidazole 400 mg twice daily and clarithromycin 250 mg twice daily.

Long-term management
Capsules should only be used in certain situations including:

- In patients who have recurrent peptic ulceration where the pathogenesis of the ulcer is not related to H. pylori infection; or
- Where repeated eradication therapy is unsuccessful; or
- Patients who have a past history of perforation or bleeding from an ulcer.

Special populations

Renal impairment
There is no need to alter the dosage in patients with impaired renal function.

Hepatic impairment
Lansoprazole is metabolised substantially by the liver. The results of clinical trials in patients with liver disease indicate that the metabolism of lansoprazole is prolonged in patients with severe hepatic impairment. However, no dose adjustment is necessary in these patients, although the daily dose should not exceed 30 mg.

4.3 Contraindications
Hypersensitivity to lansoprazole or other proton pump inhibitors or to any of the excipients listed in section 6.1.

Severe hepatic impairment.

4.4 Special warnings and precautions for use

General
As with other anti-ulcer therapies, the possibilities of malignancy should be excluded when a gastric ulcer is suspected, since treatment with lansoprazole may alleviate the symptoms of a malignancy and possibly delay its diagnosis.

Enterochromaffin-like cell effects (ECL)
Safety concerns of long term treatment relate to hypergastrinaemia and possible ECL effects. ECL cell hyperplasia and gastric carcinoid tumour were observed in animal studies (see section 5.3).

Human gastric biopsy specimens from patients treated with proton pump inhibitors have not detected ECL cell effects similar to those seen in rats. Gastric biopsies taken in all the long-term maintenance studies have revealed:

- A slight increase in mean endocrine cell count during 12 months maintenance treatment with lansoprazole 15 mg or 30 mg, observed in 3 of 4 studies. Cell density averages were slightly higher under 30 mg lansoprazole than under 15 mg lansoprazole once daily. These observations were reversible approximately 3 months after maintenance therapy stopped in two of the studies.
- Single cases of changes from normal to simple hyperplasia which persisted in one patient 3 months after discontinuation of treatment.
- For antral biopsies a greater mean gastrin-positive cell density and mean serotonin-positive cell density was found for lansoprazole 30 mg compared to lansoprazole 15 mg once daily.
- No evidence of carcinoid tumours or visible endocrine cell proliferation was seen in any patient for either fundus or antral biopsies.

(There are currently biopsy data on over 400 patients treated between 9 months and one year and over 230 patients treated for more than one year.)

**Hypomagnesaemia**

Hypomagnesaemia, symptomatic and asymptomatic, has been reported rarely in patients treated with PPIs for longer than three months. In severe cases hypocalcaemia was also reported. Serious adverse events include tetany, arrhythmias and seizures. In some patients, treatment of hypomagnesaemia with magnesium replacement was not sufficient to correct the magnesium imbalance and discontinuation of the PPI was required. In patients later retreated with the same or different PPI, hypomagnesaemia returned within a shorter time period.

For patients expected to be on prolonged treatment or who take PPIs with other medicines such as digoxin or medicines that may cause hypomagnesaemia, consideration should be given to monitoring magnesium levels prior to initiation and periodically thereafter.

**Risk of fractures**

Proton pump inhibitors, especially if used in high doses and over long durations (>1 year), may modestly increase the risk of hip, wrist and spine fracture, predominantly in the elderly or in presence of other recognised risk factors. Observational studies suggest that proton pump inhibitors may increase the overall risk of fracture by 10–40%. Some of this increase may be due to other risk factors. Patients at risk of osteoporosis should receive care according to current clinical guidelines and they should have an adequate intake of vitamin D and calcium.

**Subacute Cutaneous Lupus Erythematosus (SCLE)**

Proton pump inhibitors are associated with very infrequent cases of SCLE. If lesions occur, especially in sun-exposed areas of the skin, and if accompanied by arthralgia, the patient should seek medical help promptly and the healthcare professional should consider stopping lansoprazole. SCLE after previous treatment with a proton pump inhibitor may increase the risk of SCLE with other proton pump inhibitors.

**Retinal atrophy**

In animal studies, retinal atrophy was observed in Sprague Dawley rats dosed orally with lansoprazole. Retinal atrophy has not been found in mice, dogs, monkeys or humans. Mechanistic studies have indicated that the effect is specific to species dependent on hepatic synthesis of the amino acid taurine, which has a protective effect on the retina. Lansoprazole inhibits hepatic synthesis of taurine, however, humans obtain their taurine requirements from the diet.
Use in children
The use of LANZOL RELIEF is not recommended in children as clinical data are limited. Treatment of small children below one year of age should be avoided as available data have not shown beneficial effects in the treatment of gastro-oesophageal reflux disease.

Elderly
Dosage adjustment is not required in the elderly.

Other precautions
Agents that elevate gastric pH may increase the already-present risk of nosocomial pneumonia in intubated ICU patients receiving mechanical ventilation.

When using lansoprazole with antibiotics to eradicate *H. pylori*, it is recommended that prescribers refer to the approved product information for the antibiotics selected. Decreased gastric acidity due to any means, including proton pump inhibitors, increases gastric counts of bacteria normally present in the gastrointestinal tract. Treatment with acid-reducing drugs may lead to a slightly increased risk of gastrointestinal infections such as *Salmonella* and *Campylobacter* and, in hospitalised patients, possibly also *Clostridium difficile*.

4.5 Interaction with other medicines and other forms of interaction

Lansoprazole is metabolised in the liver and is a weak inducer of cytochrome P450. Therefore, there is the possibility of interaction with other drugs metabolised via this system e.g. theophylline. Patients receiving such drugs concomitantly with lansoprazole should be monitored to determine if any dosage adjustment is necessary.

No clinically significant effects on plasma levels of warfarin, phenytoin (single IV doses only) and diazepam have been found.

The possibility of interaction between lansoprazole and low dose oral contraceptives cannot be excluded.

There is no evidence of an interaction between lansoprazole and non-steroidal anti-inflammatory drugs or antacids.

Co-administration of lansoprazole with sucralfate delayed absorption and reduced lansoprazole bioavailability by approximately 30%. Therefore, lansoprazole should be taken at least 30 minutes prior to sucralfate.

Lansoprazole causes a profound and long lasting inhibition of gastric acid secretion; therefore, it is theoretically possible that lansoprazole may interfere with the absorption of drugs where gastric pH is an important determinant of bioavailability (e.g. ketoconazole, ampicillin esters, iron salts, digoxin).

**Methotrexate**

When given together with proton pump inhibitors, methotrexate levels have been reported to increase in some patients. In high-dose methotrexate administration a temporary withdrawal of the proton pump inhibitor may need to be considered.

4.6 Fertility, pregnancy and lactation

**Pregnancy**

Pregnancy category B3

Lansoprazole has been taken by only a limited number of pregnant women and women of childbearing age, without an increase in the frequency of malformation or other direct or indirect harmful effects on the human foetus having been observed.
Breast-feeding
Animal studies indicate that lansoprazole is secreted into breast milk. There is no information on the secretion of lansoprazole into breast milk in humans. The use of lansoprazole during breast feeding should be avoided.

Fertility
For pre-clinical fertility data refer to section 5.3.

4.7 Effects on ability to drive and use machines
Lansoprazole is likely to produce minor or moderate influence on the ability to drive or use machinery.

4.8 Undesirable effects
Lansoprazole is well tolerated. A low incidence of events has been reported during clinical trials in 7,867 patients treated with lansoprazole. These events, which are generally transient and self-limiting, include headache, diarrhoea, abdominal pain, dyspepsia, nausea, vomiting, dizziness, constipation, flatulence, rash, upper respiratory tract infections, urinary tract infections, arthralgia and myalgia. Dermatological reactions include urticaria and pruritus. These generally resolve on discontinuation of drug therapy. Serious dermatological reactions are rare but there have been occasional reports of erythematous or bullous rashes including erythema multiforme. Cases of hair thinning and photosensitivity have also been reported. Other reported reactions include jaundice, hepatitis, interstitial nephritis (sometimes resulting in renal failure), anaphylaxis, wheezing, angioedema, bruising, purpura, petechiae, depression, peripheral oedema, paraesthesia, blurred vision, taste disturbances, vertigo, confusion and hallucinations. Gynaecomastia and impotence may occur with long term use. During clinical trials a small number of patients developed abnormal liver function tests (predominantly gamma-GT) while on lansoprazole, however, routine monitoring of liver function tests is not required.

Isolated cases of blood dyscrasias, such as thrombocytopenia, leukopenia, neutropenia, agranulocytosis and pancytopenia have been reported, but a definite relationship to lansoprazole therapy has not been established.

Metabolism and nutritional disorders
Frequency not known: Hypomagnesaemia (see section 4.4).

Musculoskeletal disorders
Frequency (uncommon, > 1/1,000, < 1/100): Fracture of the hip, wrist or spine (see section 4.4).

Skin and subcutaneous tissue disorders
Frequency not known: Subacute cutaneous lupus erythematosus.

Worldwide, there has been one report of acute colitis occurring in a 52-year-old male patient after treatment with 60 mg/day lansoprazole for six weeks.

As with any broad-spectrum antibiotic treatment, the risk of pseudomembranous colitis should be considered in patients using triple therapy for the eradication of H. pylori.

Reporting of suspected adverse reactions
Reporting suspected adverse reactions after authorisation of the medicine is important. It allows continued monitoring of the benefit/risk balance of the medicine. Healthcare professionals are asked to report any suspected adverse reactions https://nzphvc.otago.ac.nz/reporting/.

4.9 Overdose
There is no information on the effect of acute over dosage. In case of overdose, supportive and symptomatic therapy should be initiated.

Doses of up to 180 mg/day for more than a year have been used to treat Zollinger Ellison Syndrome with no serious adverse effects.

For further advice on management of overdose please contact the National Poisons Information Centre (0800 POISON or 0800 764 766).

5. Pharmacological Properties

5.1 Pharmacodynamic properties

Pharmacotherapeutic group: drugs for peptic ulcer and gastro-oesophageal reflux disease (GORD), ATC code: A02BC03

Mechanism of action

Lansoprazole reduces gastric acid secretions by inhibiting the H⁺/K⁺-ATPase (proton pump) of the parietal cells in the gastric mucosa, the terminal phase of acid secretion. The drug is effective in the treatment of acid-related disorders of the upper gastrointestinal tract.

A single dose of 30 mg lansoprazole inhibits stimulated acid secretion by approximately 80%. Basal acid secretion and basal and stimulated secretion volumes are affected to a lesser degree.

After repeated dosing (for 7 days) 90% inhibition of stimulated acid secretion is achieved. Despite its short elimination half-life, lansoprazole has a prolonged pharmacological action, providing effective suppression of gastric acid secretion over 24 hours.

When used in combination with the recommended antibiotics, it is associated with *H. pylori* eradication rates of up to 90%.

Clinical efficacy and safety

*Helicobacter Pylori*

In clinical trials, the recommended dosage regimens were associated with *H. Pylori* eradication rates of up to 90%. The best eradication rates were obtained with regimens which included clarithromycin. Trials, which used Lansoprazole 30 mg capsules in combination with only one antibiotic, resulted in significantly lower eradication rates. Therefore, such regimens are not recommended.

*Reflux oesophagitis*

In two double-blind, placebo controlled multicentre studies (of 336 patients) examining the efficacy of lansoprazole 15 mg and 30 mg tablets in maintaining healed erosive reflux oesophagitis, lansoprazole was significantly superior to placebo in maintaining endoscopic and symptomatic freedom from disease. The time to median recurrence of either symptoms or endoscopic evidence of disease was less than 1 month for the placebo and greater then 12 months for 15 mg and 30 mg lansoprazole (*p* ≤ 0.001). There was a slight trend for a better outcome with 30 mg lansoprazole although this was not statistically significant.

A study in 266 patients comparing lansoprazole 15 mg and 30 mg daily with ranitidine 300 mg twice daily, found both lansoprazole 15 mg and 30 mg increased the time to relapse and probability of no relapse in comparison to ranitidine. The percentage of patients who relapsed endoscopically during the 12-month maintenance period was 31% in the lansoprazole 15 mg group, 20% in the lansoprazole 30 mg group and 68% in the ranitidine group. The difference between the lansoprazole groups and the ranitidine was apparent from the earliest time point in the study and maintained throughout the 12-month period. Comparison of treatment groups with regard to
symptom control showed similar superiority of lansoprazole over ranitidine ($p \leq 0.001$ for each comparison).

A study in 882 patients comparing lansoprazole 15 mg and 30 mg daily with omeprazole 20 mg daily showed endoscopic remission rates (after 12 months) of 75% with lansoprazole 15 mg daily, 88% with lansoprazole 30 mg daily and 89% with omeprazole 20 mg daily. The results demonstrate that lansoprazole 30 mg daily achieved significantly better remission rates compared to lansoprazole 15 mg daily and is of equal efficacy to omeprazole 20 mg daily.

The results of the 4 pivotal studies examining the use of lansoprazole in the long-term management of reflux oesophagitis are tabulated below:

### Endoscopically proven relapse rates at 12 months

# ($p \leq 0.001$) versus omeprazole 20 mg and lansoprazole 30 mg

### Duodenal ulcer

In a study comparing lansoprazole 15 mg daily with placebo in 180 patients with endoscopically documented duodenal ulcer, the percentage of patients who remained healed after twelve months was significantly higher with lansoprazole than with placebo. Lansoprazole 15 mg was significantly superior to placebo in preventing endoscopic and symptomatic relapses of disease.

| Duodenal ulcer recurrence rates |
|-------------------------------|-----------------|
| Treatment                     | Interval (months) |
|                               | 0-1   | 1-2   | 2-3   | 3-6   | 6-9   | 9-12  |

*($p < 0.001$) versus placebo

The maintenance studies discussed, using lansoprazole 15 mg and 30 mg did not extend beyond 12 months.

### 5.2 Pharmacokinetic properties

#### Absorption

Lansoprazole is well absorbed and exhibits high bioavailability (80-90%) following an oral dose. The bioavailability has been shown to be affected by the presence of food, however, acid inhibition (which is an endpoint for efficacy), as measured from sampling of gastric juice in healthy volunteers, is not significantly affected by food. It was shown in one study that morning dosing produced higher mean gastric pH values than afternoon dosing.

#### Distribution

Plasma protein binding is high (98%) and is gender and concentration independent. Binding does not change as a result of multiple dosing. The plasma elimination half-life in healthy subjects
ranges from 1 to 2 hours following a single dose or multiple doses. Peak plasma levels occur within
1.5 to 2.0 hours after dosing in these subjects.

After IV administration, the volume of distribution is 29 ± 4 L, total clearance is 31 ± 8 L/h and
elimination half-life is 0.9 ± 0.44 hours.

Elimination
Following absorption, lansoprazole is extensively metabolised and the metabolites are excreted by
both the renal and biliary route. A study with $^{14}$C-labelled lansoprazole showed that up to 50% of
the label was excreted in the urine, although unchanged drug does not appear to be excreted by
this route; unchanged drug is eliminated, however, by biliary excretion.

5.3 Preclinical safety data

Fertility
Reproductive studies conducted in pregnant rats and rabbits at oral doses up to 300 and
30 mg/kg/day, respectively, did not disclose any evidence of a teratogenic effect. A significant
increase in foetal mortality was observed in the rabbit study at doses above 10 mg/kg/day. In rats a
slight reduction in litter survival and weights was noted at doses above 100 mg/kg/day.

The effects of lansoprazole on human male fertility have not been evaluated.

Carcinogenicity
In a 2 year carcinogenicity study in rats, oral doses of 5, 15 or 50 mg/kg/day, 5 days per week
produced gastric ECL cell hyperplasia and carcinoid tumours in a dose-related manner in both
male and female rats. The incidence of these effects was markedly higher in female rats. A "no effect"
dose was not established for female rats. An increased incidence of benign Leydig cell
tumours and testicular hyperplasia was also reported at dose levels of 15 mg/kg/day. Two repeat 2
year carcinogenicity studies in rats using doses ranging from 5-150 mg/kg/day, 7 days per week
confirmed these findings.

In mice, a 78 week carcinogenicity study was performed at doses of 1.5, 5, 15 and 50 mg/kg/day, 5
days per week. No gastric ECL cell carcinoids were seen. In a repeat carcinogenicity study, mice
were dosed with 15, 75, 150 or 300 mg/kg/day, 7 days a week. Terminal studies showed ECL cell
hyperplasia, mucosal hyperplasia/hypertrophy and glandular dilatation and vacuolisation at all
dosages. Carcinoids were found in occasional animals receiving 15, 150 or 300 mg/kg/day.

Hypergastrinaemia secondary to prolonged hypochlorhydria has been postulated to be the
mechanism by which ECL cell hyperplasia and gastric carcinoid tumours develop.

Mutagenicity
Negative results were obtained in gene mutation assays and in an in vivo assay of chromosomal
damage. In vitro assays of chromosomal damage showed evidence of chromosomal aberrations,
though this may reflect cytotoxicity rather than genotoxic activity.

6. Pharmaceutical Particulars

6.1 List of excipients
LANZOL RELIEF capsules contain as excipients: sugar spheres, heavy magnesium carbonate,
sucrose, corn starch, hydroxypropyl cellulose, methacrylic acid-ethyl acetate copolymer, talc,
polyethylene glycol, titanium dioxide, polysorbate 80 and colloidal anhydrous silica.

The hard gelatin capsules contain gelatin and titanium dioxide and are imprinted with Tek Print Ink
SW-9009.
Additionally the 15 mg gelatin capsules contain the following permitted colourants, FD & C Green # 3 and FD & C Red # 40 and the 30 mg gelatin capsules FD & C Blue # 1 and FD & C Red # 3.

LANZOL RELIEF capsules are lactose free and gluten free.

6.2 Incompatibilities
Not applicable.

6.3 Shelf life
3 years.

6.4 Special precautions for storage
Store at or below 25°C.

6.5 Nature and contents of container
15 mg capsules are available in blister packs containing 28 or 30 capsules, or bottles containing 30, 100, 500, 1000 capsules.

30 mg capsules are available in blister packs containing 28 or 30 capsules, or bottles containing 30, 100, 500, 1000 capsules.

Not all pack types and sizes may be marketed.

6.6 Special precautions for disposal
Not applicable.
