

## NEW ZEALAND DATA SHEET

### 1. BENTROP TABLET

Benztrop tablet 2mg

### 2. QUALITATIVE AND QUANTITATIVE COMPOSITION

Benztrop 2mg: Each tablet contains 2mg of benztropine mesilate.

#### Excipients with known effect:

Maize starch, lactose, microcrystalline cellulose, and magnesium stearate.

For full list of excipients, see section 6.1.

### 3. PHARMACEUTICAL FORM

Tablet.

BENZTROP 2 mg tablets are round, flat-faced, cross-scored on one side and embossed “PMS-2” on the other side.

### 4. CLINICAL PARTICULARS

#### 4.1 Therapeutic indications

BENZTROP tablets are indicated for the treatment of all forms of Parkinsonism and the treatment of extrapyramidal reactions (except tardive dyskinesia [see Contraindications and Warnings and Precautions]) due to neuroleptic drugs.

#### 4.2 Dose and method of administration

Benzatropine action is cumulative and therapy should be initiated with a small dose, which can be increased gradually at five- or six-day intervals, to a maximum of 6 mg.

Dose equivalence when the tablet is quartered has not been established. This product is not able to deliver all approved dose regimens.

Some patients experience greatest relief when taking the entire dose at bedtime; others react more favourably to divided doses, two to four times a day.

The long duration of action of BENZTROP makes it particularly suitable for administration at bedtime when the effects may persist throughout the night. Therefore, BENZTROP enables the patient to turn in bed more easily and to rise in the morning.

When BENZTROP is started, therapy with other agents in Parkinsonism should not be terminated abruptly but reduced or discontinued gradually. Many patients obtain the greatest relief with a combination of BENZTROP and other drugs.

BENZTROP may be used concomitantly with SINMET\* (carbidopa/ levodopa, MSD), or with levodopa in which case periodic dosage adjustment may be required in order to maintain optimum response.

### Arteriosclerotic, Idiopathic and Postencephalitic Parkinsonism

The usual daily dose of benztropine is 1 mg to 2 mg, with a range of up to 6 mg orally. Dosage must be individualised. In determining the dosage, the age and weight of the patient and the type of Parkinsonism must be taken into consideration. Older patients, thin patients and patients with arteriosclerotic Parkinsonism generally cannot tolerate large doses. However, most patients with postencephalitic Parkinsonism require and, indeed, tolerate fairly large doses. Patients with a poor mental outlook are usually poor candidates for therapy.

In arteriosclerosis and idiopathic Parkinsonism, therapy may be initiated with a single daily dose of 1 mg at bedtime. This dosage will be adequate in some patients, whereas 4 mg to 6 mg a day may be required by others.

Therapy may be initiated in most patients with postencephalitic Parkinsonism, with 2 mg a day in one or more doses.

### Drug-Induced Parkinsonism

When treating extrapyramidal disorders due to central nervous system drugs such as phenothiazines or reserpine, a dosage of 1 to 4 mg once or twice a day is recommended. Dosage should be varied to suit the needs of the patient. BENZTROP should be withdrawn to determine the continued need for medication after one or two weeks of administration. If Parkinsonism recurs therapy with BENZTROP can be reinstated.

### **4.3 Contraindications**

BENZTROP is contraindicated in children under three years of age, and should be used with caution in older children because of the atropine-like side effects.

BENZTROP is contraindicated in patients who are hypersensitive to any component in this product.

The use of BENZTROP is contraindicated in the presence of narrow angle glaucoma.

BENZTROP should not be used in patients with tardive dyskinesia as it can exacerbate this condition.

### **4.4 Special warnings and precautions for use**

BENZTROP has cumulative action. Patients with a tendency to tachycardia and patients with prostatic hypertrophy must be closely observed during treatment.

BENZTROP may cause complaints of weakness and inability to move particular muscle groups in large doses. For example, if the neck has been rigid and suddenly relaxes, it may feel weak, causing some concern. In this event, dosage adjustment may be required.

With large doses, mental confusion and excitement may occur or in susceptible patients. Visual hallucinations have been reported occasionally. In the treatment of extrapyramidal symptoms due to central nervous system drugs, such as phenothiazines, in patients with mental disorders, occasionally there may be intensification of mental disorders with large doses. In such cases antiparkinsonian drugs can precipitate a toxic psychosis. Patients with mental disorders should be kept under careful observation, especially at the beginning of treatment or if dosage is increased.

Tardive dyskinesia may appear in some patients on long-term therapy with phenothiazines and related agents, or may occur after therapy when these drugs have been discontinued. Antiparkinsonian agents usually do not alleviate their symptoms of tardive dyskinesia, and in some instances may aggravate or unmask such symptoms.

BENZTROP is not recommended in tardive dyskinesia.

As benztropine contains structural features of atropine, it may produce anhydrosis. Therefore, it should be given with caution during hot weather, especially when given concomitantly with other atropine-like drugs to the chronically ill, the alcoholic, those who have central nervous system disease and those who do manual labour in a hot environment. When some disturbance of sweating already exists, anhydrosis may occur more readily. If there is evidence of anhydrosis, the possibility of hyperthermia should be considered. Dosage should be decreased at the discretion of the physician so that the ability to maintain body heat equilibrium by perspiration is not impaired. Severe anhydrosis and fatal hyperthermia have occurred.

The physician should be aware of the possible occurrence of glaucoma. Although the drug does not appear to have any adverse effect on simple glaucoma, it should not be used in narrow-angle glaucoma. (*see Contraindications*).

Dysuria may occur but rarely becomes a problem. Urinary retention has been reported with benztropine.

BENZTROP should be used with caution in patients with obstructive gastrointestinal disease as benztropine may cause decrease motility and tone which may aggravate or precipitate obstruction.

#### **4.5 Interaction with other medicines and other forms of interaction**

When BENZTROP is given concomitantly with anticholinergics or those with antidopaminergic activity, such as phenothiazines, haloperidol or other such drugs, patients should be advised to report fever, heat intolerance and gastrointestinal complaints promptly. Paralytic ileus, sometimes fatal, has occurred in patients taking anticholinergic-type antiparkinsonism drugs, including BENZTROP, in combination with phenothiazines and/or tricyclic antidepressants.

Alcohol and other CNS depressants, such as anxiolytics, sedatives and hypnotics, can increase the sedative effects of benztropine. Drugs that exert anticholinergic properties may pharmacodynamically oppose the effects of prokinetic agents such as cisapride or metoclopramide. The doses of BENZTROP and levodopa must be adjusted when the drugs are given simultaneously. Through its central anticholinergic actions BENZTROP can potentiate the dopaminergic effects of levodopa. While some patients may benefit from this interaction,

clinicians should be ready to decrease doses of levodopa if benztropine is added. The anticholinergic properties of BENZTROP, by slowing GI transit, may decrease levodopa bioavailability. However, this mechanism appears to be of modest clinical significance. Anticholinergics can raise intragastric pH. This effect may interfere with the oral bioavailability of metoconazole. BENZTROP should be used cautiously in patients receiving ketoconazole.

Opiate agonists should be used cautiously with anticholinergics since additive depressive effects on GI motility or bladder function may be seen. The muscarinic actions of drugs known as parasympathomimetics, including both direct cholinergic receptor agonists and cholinesterase inhibitors, can antagonise the anticholinergic actions of benztropine. Benztropine might also antagonise some of the effects of the parasympathomimetics. Carbonic anhydrase inhibitors increase the alkalinity of the urine, thereby increasing the amount of nonionized drug available for renal tubular reabsorption.

Use with caution if BENZTROP is administered with carbonic anhydrase inhibitors, which can decrease excretion and enhance the effects of BENZTROP. Monitor for excessive anticholinergic Adverse Effects.

## **4.6 Fertility, pregnancy and lactation**

### Use in Pregnancy (Category B2)

It is not known whether BENZTROP can cause foetal harm when administered to a pregnant woman, or if it can affect reproductive capacity. The safe use of Benztropine in pregnancy has not been established.

### Use in Lactation

It is not known whether BENZTROP is excreted in breast milk. Because many drugs are excreted in human milk, caution should be exercised if BENZTROP is administered to a breast-feeding woman.

## **4.7 Effects on ability to drive and use machines**

BENZTROP may impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle.

## **4.8 Undesirable effects**

Adverse reactions, most of which are anticholinergic or antihistaminic in nature are listed below by body system in order of decreasing severity:

Cardiovascular: Tachycardia

Digestive: Constipation, dry mouth, nausea, vomiting, paralytic ileus. Reduce dosage, or discontinue the drug temporarily if dry mouth is so severe that there is difficulty in swallowing or speaking, or loss of appetite and weight occur.

Slight reduction in dosage may control nausea and still give sufficient relief of symptoms. Vomiting may be controlled by temporary discontinuation, followed by resumption at a lower dosage.

Nervous System: Toxic psychosis, including confusion, disorientation, memory impairment, visual hallucinations, exacerbation of pre-existing psychotic symptoms, nervousness, depression, listlessness, numbness of fingers.

Special Senses: Dilated pupils, blurred vision.

Urogenital: Urinary retention, dysuria.

Metabolic / Immune and Skin: Occasionally, an allergic reaction e.g. skin rash, develops. If this cannot be controlled by dosage reduction, the medication should be discontinued.

Other: Heat stroke, hyperthermia, fever.

## **4.9 Overdose**

Manifestations: As with any of those seen in atropine poisoning or antihistamine overdose: CNS depression, preceded or followed by stimulation; confusion; nervousness; listlessness; intensification of mental symptoms or toxic psychosis in patients with mental illness being treated with phenothiazine derivatives; hallucination (especially visual); dizziness; muscle weakness; ataxia; dry mouth; mydriasis; blurred vision; palpitations; tachycardia; nausea; vomiting; dysuria; numbness of fingers; dysphagia; allergic reactions, e.g. skin rash; headache; hot, dry, flushed skin, delirium; coma; shock; convulsions; respiratory arrest; anhydrosis; hyperthermia; glaucoma; constipation.

Treatment: Physostigmine salicylate, 1 to 2 mg s.c. or i.v., will reverse symptoms of anticholinergic intoxication. A second injection may be given after two hours if required. Otherwise treatment is symptomatic and supportive. Activated charcoal should be administered within one hour of ingestion and supportive therapy should be given as required. Maintain respiration. A short-acting barbituate may be used for CNS excitement, depression (avoid convulsant stimulants such as picrotoxin, pentylenetetrazole or bemegride); artificial respiration for severe respiratory depression; a local miotic for mydriasis and cycloplegia; ice bags or other cold applications and alcohol sponges for hyperpyrexia, a vasopressor and fluids for circulatory collapse. Darken room for photophobia.

## **5. PHARMACOLOGICAL PROPERTIES**

### **5.1 Pharmacodynamic properties**

Benzatropine is a centrally acting anticholinergic agent with antihistaminic properties resulting from the combination of the tropine portion of the atropine molecule and the benzohydril portion of diphenhydramine. Animal studies have indicated that anticholinergic activity of benztropine is approximately half that of atropine, while antihistaminic activity approaches that of pyrilamine. Its anticholinergic effects have been established as therapeutically significant in the management of Parkinsonism. Benzatropine antagonises the effect of acetylcholine, decreasing the imbalance between the neurotransmitters acetylcholine and dopamine, which may improve the symptoms of early Parkinson's disease.

### **5.2 Pharmacokinetic properties**

Benzatropine is absorbed from the GI tract, crosses the blood-brain-barrier, and may cross the placenta. After oral administration, a small part of the dose may pass through the GI tract unchanged into the faeces. It binds extensively, approximately 95 %, with serum proteins. The metabolism of benztropine is unknown, but most of the drug is excreted renally, both as a parent drug and as metabolites.

### **5.3 Preclinical safety data**

Non-clinical data reveal no special hazard for humans based on conventional studies of safety pharmacology, repeated dose toxicity, genotoxicity, carcinogenic potential, toxicity to reproduction and development.

## **6. PHARMACEUTICAL PARTICULARS**

### **6.1 List of excipients**

#### Other excipient

Magnesium stearate, microcrystalline cellulose, pregelatinised maize starch.

#### Other excipient – animal origin

Lactose.

### **6.2 Incompatibilities**

Not applicable.

### **6.3 Shelf life**

24 months from date of manufacture.

#### **6.4 Special precautions for storage**

Store at or below 25°C.

#### **6.5 Nature and contents of container**

Benzotrop tablets are supplied in bottles of 60.

#### **6.6 Special precautions for disposal**

No special requirements.

### **7. MEDICINE SCHEDULE**

Prescription medicine.
