1 PRODUCT NAME

AVELOX 400 mg moxifloxacin film coated tablet

AVELOX 400 mg moxifloxacin solution for infusion

2 QUALITATIVE AND QUANTITATIVE COMPOSITION

Each tablet contains 436.8 mg moxifloxacin hydrochloride, equivalent to 400 mg moxifloxacin.

Each 250 mL solution for infusion contains 436.8 mg moxifloxacin hydrochloride, equivalent to 400 mg moxifloxacin in 0.8% sodium chloride. The solution for infusion (250 mL) contains 34 mmol sodium.

For the full list of excipients, see Section 6.1 List of excipients.

3 PHARMACEUTICAL FORM

The film coated tablets are dull red, oblong and convex, 17 x 7 mm with 10 mm radius of curvature weighing 693.8 – 699.8 mg. They are marked “Bayer” on one side and “M 400” on the other side.

The IV infusion is available in either a polyolefine flexible bag or a glass bottle filled with a minimum of 250 mL clear, yellow solution.

4 CLINICAL PARTICULARS

4.1 Therapeutic indications

Avelox tablets and solution for infusion are indicated for the treatment of the following bacterial infections caused by susceptible strains:

- Bronchitis (acute exacerbations of chronic bronchitis)
- Pneumonia (community acquired)
- Sinusitis (acute)
- Complicated skin and skin structure infections (including diabetic foot infections)
- Complicated intra-abdominal infections including polymicrobial infections such as abscesses

Avelox tablets are indicated for the treatment of the following bacterial infections caused by susceptible strains:

- Uncomplicated pelvic inflammatory disease (i.e. infections of female upper genital tract, including salpingitis and endometritis)
Consideration should be given to available official guidance on the appropriate use of antibacterial agents.

4.2 Dose and method of administration

Dose
The recommended dose for Avelox is 400 mg once daily (1 film-coated tablet or 250 mL solution for infusion) for the above-mentioned indications and should not be exceeded.

Duration of Treatment
The duration of treatment should be determined by the severity of the indication or clinical response. The following are general recommendations:

- **Film-coated tablet**
  - Bronchitis: acute exacerbation of chronic bronchitis, 5 days
  - Pneumonia: community acquired pneumonia, 10 days
  - Sinusitis: acute sinusitis, 7 days
  - Complicated skin and skin structure infections total treatment duration for sequential therapy (intravenous followed by oral therapy): 7 – 21 days
  - Uncomplicated pelvic inflammatory disease: 14 days
  - Complicated intra-abdominal infections total treatment duration for sequential therapy (intravenous followed by oral therapy): 5 – 14 days

- **Solution for infusion**
  - Bronchitis: acute exacerbation of chronic bronchitis, 5 days
  - Pneumonia: community acquired pneumonia (intravenous followed by oral therapy), 7-14 days
  - Sinusitis: acute sinusitis, 7 days
  - Complicated skin and skin structure infections total treatment duration for sequential therapy (intravenous followed by oral therapy): 7 – 21 days
  - Complicated intra-abdominal infections total treatment duration for sequential therapy (intravenous followed by oral therapy): 5 – 14 days

Avelox can be administered intravenously for the entire treatment duration. Alternatively, therapy may be initial intravenous administration, followed by oral administration of film-coated tablets when clinically indicated.

The recommended duration of treatment for the indication being treated should not be exceeded.

Avelox 400 mg film-coated tablets and Avelox 400 mg solution for infusion have been studied in clinical trials for up to 21 days (in complicated skin and skin structure infections).

*Geriatric Patients*
No adjustment of dosage is required in the elderly.
Paediatric population
Efficacy and safety of Avelox in children and adolescents have not been established (see also Section 4.3 Contraindications).

Ethnic Differences
No adjustment of dosage is required in ethnic groups.

Patients with Hepatic Impairment
No dosage adjustment is required in patients with impaired liver function (see Section 4.4 Special warnings and precautions for use, for patients with liver cirrhosis).

Patients with Renal Impairment
No dose adjustment is required for patients with renal impairment (including creatinine clearance ≤ 30 mL/min/1.73m²) and in patients on chronic dialysis i.e. haemodialysis and continuous ambulatory peritoneal dialysis.

Method of Administration

Film-coated tablet
The film-coated tablet should be swallowed whole with sufficient liquid and may be taken independently of meals.

Solution for infusion
The solution for infusion should be infused intravenously over 60 minutes.

The solution for infusion can be administered directly or via a T-tube together with compatible infusion solutions.

The following co-infusions were found to form stable mixtures over a period of 24 hours at room temperature with Avelox solution for infusion, and can therefore be considered as compatible with Avelox solution for infusion:

- Water for Injections
- Sodium Chloride 0.9%
- Sodium Chloride 1 molar
- Glucose 5%
- Glucose 10%
- Glucose 40%
- Xylitol 20%
- Ringer’s Solution
- Lactated Ringer’s Solution

If Avelox solution for infusion is to be given with another medicine, each medicine should be given separately (see also Section 6.2 Incompatibilities).

Only clear solutions are to be used.

4.3 Contraindications

Known hypersensitivity to moxifloxacin or other quinolones or any of the excipients.
Pregnancy and lactation.

Patients below 18 years of age.

4.4 Special warnings and precautions for use

Fluoroquinolones, including moxifloxacin, have been associated with disabling and potentially persistent adverse reactions involving different body systems that have occurred together in the same patient. These include, but are not limited to, serious adverse reactions involving the nervous system and musculoskeletal system.

In some instances, the hypersensitivity and allergic reactions occurred after the first administration and the doctor should be informed immediately.

Anaphylactic reactions in very rare instances can progress to a life threatening shock, in some instances after the first administration. In these cases the treatment with Avelox must be discontinued, medical treatment (e.g. treatment for shock) is required.

Avelox has been shown to prolong the QT interval of the electrocardiogram in some patients. As women tend to have a longer baseline QTc interval compared with men, they may be more sensitive to QTc-prolonging medications. Elderly patients may also be more susceptible to drug-associated effects on the QT interval. As the magnitude of QT prolongation may increase with increasing concentrations of the medicine, the recommended dose and the infusion rate (400 mg within 60 minutes) should not be exceeded. However, in patients suffering from pneumonia, no correlation between plasma concentrations of moxifloxacin and QTc prolongation was observed. QT prolongation may lead to an increased risk for ventricular arrhythmias including torsades de pointes. No cardiovascular morbidity or mortality attributable to QTc prolongation occurred with Avelox treatment in clinical studies with more than 9000 patients; however certain predisposing conditions may increase the risk for ventricular arrhythmias.

Therefore, treatment with Avelox should be avoided due to the lack of clinical experience with the medicine in these patient populations:

- In patients with known prolongation of the QT interval
- In patients with uncorrected hypokalaemia
- In patients receiving class IA (e.g. quinidine, procainamide) or class III (e.g. amiodarone, sotalol) antiarrhythmic agents

Avelox should be used with caution as an additive effect of moxifloxacin on the QT interval cannot be excluded for the following conditions:

- In patients treated concomitantly with medicines that prolong the QT interval such as cisapride, erythromycin, antipsychotics and tricyclic antidepressants
- In patients with ongoing proarrhythmic conditions such as clinically significant bradycardia, acute myocardial ischaemia
- In patients with liver cirrhosis as pre-existing QT prolongation in these patients cannot be excluded
In women and elderly patients who both may be more susceptible to QTc-prolonging medicines

Cases of fulminant hepatitis potentially leading to liver failure (including fatal cases) have been reported with Avelox (see Section 4.8 Undesirable effects). Patients should be advised to contact their doctor immediately prior to continuing treatment if symptoms related to liver failure occur.

Cases of bullous skin reactions like Stevens-Johnson syndrome or toxic epidermal necrolysis have been reported with Avelox. Patients should be advised to contact their doctor immediately prior to continuing treatment if skin and/or mucosal reactions occur.

Seizures may occur with quinolone therapy. Avelox should be used with caution in patients with known or suspected CNS disorders, which may predispose to seizures or lower the seizure threshold.

Antibiotic associated colitis has been reported with the use of broad-spectrum antibiotics including Avelox and may range in severity from mild diarrhoea to fatal colitis. Therefore it is important to consider this diagnosis in patients who develop serious diarrhoea in association with the use of Avelox. If antibiotic associated colitis is suspected or confirmed, ongoing treatment with antibacterial agents, including moxifloxacin, should be discontinued and adequate therapeutic measures should be initiated immediately. Drugs inhibiting peristalsis are contraindicated in this situation.

Avelox should be used with caution in patients with myasthenia gravis because the symptoms can be exacerbated.

Tendon inflammation and rupture may occur with quinolone therapy including moxifloxacin, particularly in elderly patients and in those treated concurrently with corticosteroids; cases occurring up to several months after completion of therapy have been reported. At the first sign of pain or inflammation, patients should discontinue treatment and rest the affected limb(s).

Quinolones have been shown to cause photosensitivity reactions in patients. However, in specially designed preclinical and clinical studies photosensitivity has not been observed with Avelox. In addition, since first marketed there has been no clinical evidence that Avelox causes photosensitivity reactions. Nevertheless, patients should be advised to avoid extensive exposure to either UV irradiation or sunlight.

For patients with complicated pelvic inflammatory disease (e.g. associated with a tubo-ovarian or pelvic abscess), for whom an intravenous treatment is considered necessary, treatment with Avelox 400 mg tablets is not recommended.

Avelox is not recommended for the treatment of MRSA infections. In case of a suspected or confirmed infection due to MRSA, treatment with an appropriate antibacterial agent should be started (see Section 5.1 Pharmacodynamic properties).
Moxifloxacin \textit{in vitro} activity may interfere with the \textit{Mycobacterium} spp. culture test by suppression of mycobacterial growth, causing false negative results in specimens from patients currently taking Avelox.

Cases of sensory or sensorimotor polyneuropathy resulting in paraesthesias, hypoaesthesias, dysaesthesias or weakness have been reported in patients receiving quinolones including Avelox. Patients under treatment with Avelox should be advised to inform their doctor prior to continuing treatment if symptoms of neuropathy such as pain, burning, tingling, numbness or weakness develop (see Section 4.8 Undesirable effects).

Psychiatric reactions may occur even after the first administration of fluoroquinolones, including moxifloxacin. In very rare cases, depression or psychotic reactions have progressed to suicidal thoughts and self-injurious behavior such as suicide attempts (see Section 4.8 Undesirable effects). In the event that the patient develops these reactions, Avelox should be discontinued and appropriate measures instituted. Caution is recommended if Avelox is to be used in psychotic patients or in patients with a history of psychiatric disease.

Because of the widespread and rising prevalence of fluoroquinolone-resistant \textit{Neisseria gonorrhoeae} infections, monotherapy with moxifloxacin should be avoided in patients with pelvic inflammatory disease, unless fluoroquinolone-resistant \textit{N. gonorrhoeae} can be excluded. If fluoroquinolone-resistant \textit{N. gonorrhoeae} cannot be excluded, the addition of an appropriate antibiotic which is regularly active against \textit{N. gonorrhoeae} (e.g. a cephalosporin) to empirical moxifloxacin therapy, should be considered.

As with all fluoroquinolones, disturbances in blood glucose, including both hypoglycaemia and hyperglycaemia, have been reported with Avelox. In Avelox-treated patients, dysglycaemia occurred predominantly in elderly diabetic patients receiving concomitant treatment with an oral hypoglycaemia agent (e.g. sulfonylurea) or with insulin. In diabetic patients, careful monitoring of blood glucose is recommended (see Section 4.8 Undesirable effects).

\textbf{Information about excipients}

In patients for whom sodium intake is of medical concern (patients with congestive heart failure, renal failure, nephrotic syndrome, etc.), the additional sodium load of the solution for infusion should be taken into account. For sodium chloride content of the solution for infusion, see Section 2 QUALITATIVE AND QUANTITATIVE COMPOSITION.

\section*{4.5 Interaction with other medicines and other forms of interaction}

For the following substances, absence of a clinically relevant interaction with Avelox was proven: atenolol, ranitidine, calcium supplements, theophylline, oral contraceptives, glibenclamide, itraconazole, digoxin, morphine, probenecid. No dose adjustment is necessary for these medicines.

\textbf{Antacids, Minerals and Multi-vitamins}

Concomitant ingestion of Avelox together with antacids, minerals and multi-vitamins may result in impaired absorption of moxifloxacin after oral administration.
due to formation of chelate complexes with the multi-valent cations contained in these preparations. This may lead to plasma concentrations considerably lower than desired. Hence, antacids, anti-retroviral medicines (e.g. didanosine), and other preparations containing magnesium or aluminium, sucralfate and agents containing iron or zinc should be administered at least 4 hours before or 2 hours after ingestion of an oral moxifloxacin dose.

Ranitidine
The concomitant administration with ranitidine did not change the absorption characteristics of moxifloxacin. Absorption parameters ($C_{\text{max}}$, $t_{\text{max}}$, AUC) were comparable indicating absence of an influence of gastric pH on moxifloxacin uptake from the GI-tract.

Calcium Supplements
When given with high dose calcium supplements, only a slightly reduced rate of absorption was observed while extent of absorption remained unaffected. The effect of high dose calcium supplements on the absorption of moxifloxacin is considered as clinically not relevant.

Theophylline
In accordance with in vitro data, no influence of moxifloxacin on theophylline pharmacokinetics and vice versa at steady state was detected in humans, indicating that moxifloxacin does not interfere with the 1A2 subtypes of the cytochrome P450 enzymes.

Warfarin
No interaction during concomitant treatment with warfarin on pharmacokinetics, prothrombin time and other coagulation parameters has been observed.

Changes in INR (International Normalised Ratio): Cases of increased anticoagulant activity have been reported in patients receiving anticoagulants concurrently with antibiotics, including Avelox. The infectious disease (and its accompanying inflammatory process), age and general status of the patient are risk factors. Although an interaction between Avelox and warfarin was not demonstrated in clinical trials, INR monitoring should be performed and, if necessary, the oral anticoagulant dosage should be adjusted as appropriate.

Oral Contraceptives
No interaction has occurred following concomitant oral administration of Avelox with oral contraceptives.

Antidiabetics
No clinically relevant interaction was seen between glibenclamide and Avelox.

Itraconazole
Exposure (AUC) to itraconazole was only marginally altered under concomitant Avelox treatment. Pharmacokinetics of moxifloxacin were not significantly altered
by itraconazole. No dose adjustment is necessary for itraconazole when given with moxifloxacin and vice versa.

**Digoxin**
The pharmacokinetics of digoxin are not significantly influenced by moxifloxacin and *vice versa*. After repeated dosing in healthy volunteers moxifloxacin increased $C_{\text{max}}$ of digoxin by approximately 30% at steady state without affecting AUC or trough levels.

**Morphine**
Parental administration of morphine with moxifloxacin did not reduce the oral bioavailability of moxifloxacin and only slightly decreased $C_{\text{max}}$ (17%).

**Atenolol**
The pharmacokinetics of atenolol are not significantly altered by moxifloxacin. Following single dose administration in healthy subjects AUC was marginally increased (by approximately 4%) and peak concentrations were decreased by 10%.

**Probenecid**
No significant effect on apparent total body clearance and renal clearance of moxifloxacin was found in a clinical study investigating the impact of probenecid on renal excretion.

**Charcoal**
Concomitant dosing of charcoal and 400 mg oral Avelox reduced the systemic availability of the medicine by more than 80% by preventing absorption *in vivo*. The application of activated charcoal in the early absorption phase prevents further increase of systemic exposure in cases of overdose.

After intravenous medicine administration carbo medicinalis only slightly reduces systemic exposure (approximately 20%).

**Food and Dairy Products**
Absorption of moxifloxacin was not altered by food intake (including dairy products). Avelox can be taken independently from food intake.

### 4.6 Fertility, pregnancy and lactation

**Pregnancy**
The safe use of Avelox in human pregnancy has not been established. Reversible joint injuries are described in children receiving some quinolones, however this effect has not been reported as occurring on exposed foetuses. Animal studies have shown reproductive toxicity. The potential risk for humans is unknown.

Consequently, the use of Avelox during pregnancy is contraindicated.

**Breastfeeding**
As with other quinolones, moxifloxacin has been shown to cause lesions in the cartilage of the weight bearing joints of immature animals. Preclinical evidence indicates that small amounts of moxifloxacin may be secreted in human milk.
There are no data available in lactating or nursing women. Therefore, the use of Avelox in nursing mothers is contraindicated.

**Fertility**

No data available.

### 4.7 Effects on ability to drive and use machines

Fluoroquinolones, including moxifloxacin, may result in an impairment of the patient's ability to drive or operate machinery due to CNS reactions and vision disorders (see Section 4.8 Undesirable effects).

### 4.8 Undesirable effects

Adverse drug reactions (ADRs) based on all clinical studies with moxifloxacin 400 mg (oral and sequential [IV/oral]/IV only administration) sorted by CIOMS III categories of frequency (overall n = 17,951, including n = 4,583 from sequential/intravenous therapy studies; status: May 2010) are listed below. ADRs listed under “common” were observed with a frequency below 3% with the exception of nausea and diarrhoea.

ADRs derived from post-marketing reports (status: May 2010) are printed in **bold italic**.

Within each frequency grouping, undesirable effects are presented in order of decreasing seriousness. Frequencies are defined as:

- **Common** ≥ 1/100 to < 1/10
- **Uncommon** ≥ 1/1000 to < 1/100
- **Rare** ≥ 1/10000 to < 1/1000
- **Very rare** < 1/10000

The following undesirable effects have a higher frequency in the subgroup of IV/oral sequentially treated patients:

- **Common:** Increased gamma-glutamyl-transferase
- **Uncommon:** Ventricular tachyarrhythmias, hypotension, oedema, vasodilatation, antibiotic associated colitis (in very rare cases associated with life threatening complications), seizures of various clinical manifestations (including grand mal convulsions), hallucination, renal impairment and renal failure (due to dehydration, especially in elderly with pre-existing renal disorders).

Reporting of suspected adverse reactions after authorisation of the medicine is important. It allows continued monitoring of the benefit/risk balance of the medicine. Healthcare professionals are asked to report any suspected adverse reactions [https://nzphvc.otago.ac.nz/reporting/](https://nzphvc.otago.ac.nz/reporting/)

### 4.9 Overdose

Only limited data on overdose are available. Single doses of up to 1200 mg and multiple doses of 600 mg moxifloxacin over 10 days were administered to healthy subjects without any significant undesirable effects. In the event of overdosage it is recommended that appropriate supportive care including ECG measurements should be instituted as dictated by the patient’s clinical status.
The use of charcoal early after oral administration may be useful to prevent excessive increase of systemic exposure to moxifloxacin in cases of overdosage.

For advice on the management of overdose, please contact the National Poisons Centre on 0800 POISON (0800 764 766)

5 PHARMACOLOGICAL PROPERTIES

5.1 Pharmacodynamic properties

Pharmacotherapeutic group

Quinolone antibacterials, fluoroquinolones
ATC Code: J01MA14

Mechanism of Action

Moxifloxacin is an 8-methoxy-fluoroquinolone antibiotic with a broad spectrum of activity and bactericidal action. Moxifloxacin has \textit{in vitro} activity against a wide range of Gram-positive and Gram-negative organisms, anaerobes, acid-fast bacteria and atypicals e.g. \textit{Chlamydia} spp., \textit{Mycoplasma} spp. and \textit{Legionella} spp.

The bactericidal action results from the interference with topoisomerase II and IV. Topoisomerases are essential enzymes that control DNA topology and assist in DNA replication, repair and transcription.

Moxifloxacin exhibits concentration dependent bactericidal killing. Minimum bactericidal concentrations are generally similar to minimum inhibitory concentrations.

Moxifloxacin is effective against $\beta$-lactam and macrolide resistant bacteria. Studies in animal models of infection have demonstrated high \textit{in vivo} activity.

5.2 Pharmacokinetic properties

Absorption

Following oral administration, moxifloxacin is absorbed rapidly and almost completely. The absolute bioavailability amounts to approximately 91%.

Pharmacokinetics are linear in the range of 50 – 1200 mg single dose and up to 600 mg once daily dosing over 10 days. Steady state is reached within 3 days. Following a 400 mg oral dose peak concentrations of 3.1 mg/L are reached within 0.5 – 4 h post application. Peak and trough plasma concentrations at steady state (400 mg once daily) were 3.2 and 0.6 mg/L, respectively.

Concomitant administration of moxifloxacin together with food slightly prolongs the time to reach peak concentrations by approximately 2 hours and slightly reduced peak concentrations by approximately 16%. Extent of absorption remained unchanged. As AUC/MIC is most predictive for antimicrobial efficacy of
quinolones, this effect is clinically not relevant. Therefore, Avelox can be administered independently from meals.

After a single 400 mg intravenous 1 hour infusion, peak concentrations of approximately 4.1 mg/L were reached in the plasma at the end of infusion which corresponds to a mean increase of approximately 26% relative to the oral application. Exposure to medicine in terms of AUC at a value of approximately 39 mg.h/L is only slightly higher compared to the exposure after oral administration (35 mg.h/L) in accordance with the absolute bioavailability of approximately 91%.

Following multiple intravenous dosing (1 hour infusion), peak and trough plasma concentrations at steady state (400 mg once daily) were between 4.1 to 5.9 mg/L and 0.43 to 0.84 mg/L, respectively. At steady-state, the exposure to medicine within the dosing interval is approximately 30% higher than after the first dose. In patients, mean steady state concentrations of 4.4 mg/L were observed at the end of a 1 hour infusion.

Distribution

Moxifloxacin is distributed very rapidly to extravascular spaces. Exposure to medicine in terms of AUC (AUCnorm = 6 kg.h/L) is high with a volume of distribution at steady state (Vss) of approximately 2 L/kg. In saliva, peak concentrations higher than those of plasma may be reached. In *in vitro* and *ex vivo* experiments over a range of 0.02 to 2 mg/L, a protein binding of approximately 45% independent from the concentration of the medicine was determined. Moxifloxacin is mainly bound to serum albumin. Due to this low value high free peak concentrations > 10 x MIC are observed.

Moxifloxacin reaches high concentrations in tissues like lung (epithelial fluid, alveolar macrophages, biotic tissue), the sinuses (maxillary and ethmoid sinus, nasal polypi) and inflamed lesions (cantharide blister fluid) where total concentrations exceeding those of the plasma concentrations are reached. High free medicine concentrations are measured in interstitial body water (saliva, intramuscular, subcutaneous). In addition, high medicine concentrations were detected in abdominal tissues and fluids and female genital tract.
Peak concentrations of moxifloxacin found in human tissues following oral (upper panel) and intravenous (lower panel) administration of a 400 mg single dose (geometric mean)

<sup>1</sup> 10 h after administration  
<sup>2</sup> unbound concentration  
<sup>3</sup> from 3 h up to 36 h post dose  
<sup>4</sup> at the end of infusion  
<sup>5</sup> 2 hours after administration  
<sup>6</sup> 3 h after administration

The peak concentrations and site vs. plasma concentration ratios for various target tissues yielded comparable results for both modes of medicine administration after a single dose of 400 mg moxifloxacin

**Metabolism**

Moxifloxacin undergoes Phase II biotransformation and is excreted via renal and biliary/faecal pathways as unchanged medicine as well as in the form of a sulfoxide compound (M1) and a glucuronide (M2). M1 and M2 are the only metabolites relevant in humans. Both are microbiologically inactive. Metabolic pharmacokinetic interactions with other medicines undergoing Phase I biotransformation involving Cytochrome P450 enzymes were not observed in in vitro or in clinical Phase I studies.

Independent from the route of administration, the metabolites M1 and M2 are found in the plasma at concentrations lower than the parent medicine. Pre-clinical investigations adequately covered both metabolites, thus excluding potential implications with respect to safety and tolerability.

**Elimination**

Moxifloxacin is eliminated from plasma with a mean terminal half-life of approximately 12 hours. The mean apparent total body clearance following a 400 mg dose ranges from 179 to 246 mL/min. Renal clearance amounted to about 24 – 53 mL/min suggesting partial tubular reabsorption of the medicine from the
kidneys. Concomitant administration of ranitidine and probenecid did not alter renal clearance of the medicine (see also table below).

Mass balance of the mother compound and Phase II metabolites of moxifloxacin yielded an almost complete recovery of approximately 96% – 98% independent from the route of administration with no indication of oxidative metabolism. A detailed overview of the mass balance according to elimination pathways (renal vs. non-renal, metabolic vs. non-metabolic) and mode of application is given in the table below.

Recovery of a 400 mg single dose (arithmetic mean ± standard deviation (SD))

Resistance

Resistance mechanisms which inactivate penicillins, cephalosporins, aminoglycosides, macrolides and tetracyclines do not interfere with the antibacterial activity of moxifloxacin. There is no cross-resistance between moxifloxacin and these agents. Plasmid-mediated resistance has not been observed to date.

It appears that the C8-methoxy moiety contributes to enhanced activity and lower selection of resistant mutants of gram-positive bacteria compared to the C8-H moiety. The presence of the bulky bicycloamine substituent at the C-7 position prevents active efflux, a mechanism of fluoroquinolone resistance.

In vitro studies have demonstrated that resistance to moxifloxacin develops slowly by multiple step mutations. A very low overall frequency of resistance was demonstrated (10⁻⁷ – 10⁻¹⁰). Serial exposure of organisms to sub-MIC concentrations of moxifloxacin showed only a small increase in MIC values.

Cross-resistance among quinolones has been observed. However, some gram-positive and anaerobic organisms resistant to other quinolones are susceptible to moxifloxacin.

Effect on the Intestinal Flora in Humans

In two volunteer studies, the following changes in the intestinal flora were seen following oral dosing with moxifloxacin. E. coli, Bacillus spp., Bacteroides vulgatus, Enterococci, and Klebsiella spp. were reduced, as were the anaerobes
Bifidobacterium, Eubacterium, and Peptostreptococcus. These changes returned to normal within two weeks. *Clostridium difficile* toxin was not found.

**/** Clinical efficacy has been demonstrated for susceptible isolates in approved clinical indications

The frequency of acquired resistance may vary geographically and with time for certain species. Local area information on resistance of organisms is desirable, particularly when treating severe infections. The above information is provided as a guide on the probability of an organism being susceptible to moxifloxacin.

Comparison of PK/PD surrogates for intravenous and oral administration of a 400 mg Avelox single dose.

In patients requiring hospitalisation, AUC/MIC<sub>90</sub> parameters greater than 125 and C<sub>max</sub> / MIC<sub>90</sub> of 8 – 10 is predictive for clinical cure (Schentag). In outpatients, these surrogate parameters are generally smaller, i.e. AUC/MIC<sub>90</sub> greater than 30 – 40 (Dudley and Ambrose).

The following table provides the respective PK/PD surrogates for intravenous and oral administration of 400 mg moxifloxacin calculated from single dose data:
Geriatric Patients

Pharmacokinetics of moxifloxacin are not affected by age.

Gender

There was a 33% difference in the pharmacokinetics (AUC, C\text{max}) of moxifloxacin between male and female subjects. Absorption was unaffected by gender. These differences in the AUC and C\text{max} were attributable to the differences in body weight rather than gender. They are not considered as clinically relevant.

Ethnic Differences

Possible interethnic differences were examined in Caucasian, Japanese, Black and other ethnic groups. No clinically relevant interethnic differences in pharmacokinetics could be detected.

Paediatric population

Pharmacokinetics of moxifloxacin were not studied in paediatric patients.

Patients with Renal Impairment

The pharmacokinetics of moxifloxacin are not significantly changed by renal impairment (including creatinine clearance < 30 mL/min/1.73m\text{2}) and in patients on chronic dialysis i.e. haemodialysis and continuous ambulatory peritoneal dialysis.

Patients with Hepatic impairment

Plasma concentrations of patients with mild to severe hepatic impairment (Child Pugh A to C) did not reveal clinically relevant differences compared to healthy volunteers or patients with normal hepatic function, respectively (see also Section 4.4 Special Warnings and Precautions for Use, in patients with liver cirrhosis).

### 5.3 Preclinical safety data

As for other quinolones, the major toxicological target organs for moxifloxacin were the haemopoietic system (hypocellularity of the bone marrow in dogs and monkeys), the central nervous system (convulsions in monkeys) and the liver (raised liver enzymes, single cell necrosis in rats, dogs and monkeys). These changes were commonly seen only after treatment with high doses of moxifloxacin or after prolonged treatment.
In a local tolerability study performed in dogs, no signs of local intolerability were seen when moxifloxacin was administered intravenously. After intra-arterial injection, inflammatory changes involving the peri-arterial soft tissue were observed suggesting that intra-arterial administration of moxifloxacin should be avoided.

**Carcinogenicity, Mutagenicity**

Although conventional long-term studies to determine the carcinogenic potential of moxifloxacin have not been performed, the medicine has been subject to a range of *in vitro* and *in vivo* genotoxicity tests. In addition, an accelerated bioassay for human carcinogenesis (initiation/promotion assay) was performed in rats. Negative results were obtained in 4 strains of the Ames test, in the HPRT mutation assay in Chinese hamster ovary cells and in the UDS assay in rat primary hepatocytes. As with other quinolones, the Ames test with TA 102 was positive and the *in vitro* test in the Chinese hamster v79 cells showed chromosomal abnormalities at high concentrations (300 µg/mL). However, the *in vivo* micronucleus assay in the mouse was negative. An additional *in vivo* assay, the dominant lethal assay in the mouse, was negative as well. It is concluded that the negative *in vivo* results adequately reflect the *in vivo* situation in terms of genotoxicity. No evidence of carcinogenicity was found in an initiation/promotion assay in rats.

**Phototoxicity**

Moxifloxacin is very photostable and has a very low potential for photogenotoxicity. *In vitro* and in animal models moxifloxacin seems to show less potency to induce phototoxicity and photogenotoxicity than other quinolones. Some quinolones have been shown to enhance the action of UV-A-induced photocarcinogenicity when administered concurrently to mice exposed to ultraviolet light. No photocarcinogenicity study has been performed with moxifloxacin. The lack of phototoxic potential has been confirmed in a Phase I study in volunteers.

**ECG**

At high concentrations, moxifloxacin is an inhibitor of the delayed rectifier potassium current of the heart and may thus cause prolongations of the QT-interval. Toxicological studies performed in dogs using oral doses of ≥ 90 mg/kg leading to plasma concentrations ≥ 16 mg/L caused QT-prolongations, but no arrhythmias. Only after very high cumulative intravenous administration of more than 50 fold the human dose (> 300 mg/kg), leading to plasma concentrations of ≥ 200 mg/L (more than 30 fold the therapeutic level after intravenous administration), reversible, non-fatal ventricular arrhythmias were seen.

**Oculotoxicity**

Toxicity tests in rats and monkeys (repeated dosing up to six months) revealed no indication regarding an oculotoxic risk. In dogs, high oral doses (≥ 60 mg/kg) leading to plasma concentrations ≥ 20 mg/L caused changes in the electroretinogram and in isolated cases an atrophy of the retina.
Arthrotoxicity

Quinolones are known to cause lesions in the cartilage of the major diarthodial joints in immature animals. The lowest oral dose of moxifloxacin causing joint toxicity in juvenile dogs was four times maximum recommended therapeutic dose (400 mg/50 kg person) on a mg/kg basis, with plasma concentrations two to three times higher than those at the recommended therapeutic dose.

Reprotoxicity

Reproductive studies performed in rats, rabbits and monkeys indicate that placental transfer of moxifloxacin occurs. Studies in rats (per os and i.v.) and monkeys (per os) did not show evidence of teratogenicity or impairment of fertility following administration of moxifloxacin. Skeletal malformations were observed in rabbits that had been treated with an intravenous dose of 20 mg/kg. This study result is consistent with the known effects of quinolones on skeletal development (see Section 4.5 Interaction with other medicines and other forms of interaction and Section 4.6 Fertility, pregnancy and lactation). There was an increase in the incidence of abortions in monkeys and rabbits at human therapeutic concentrations. In rats, decreased foetal weights, an increased prenatal loss, a slightly increased duration of pregnancy and an increased spontaneous activity of some male and female offspring were observed at doses which were 63 times the maximum recommended dose on a mg/kg basis, with plasma concentrations in the range of the human therapeutic dose.

6 PHARMACEUTICAL PARTICULARS

6.1 List of excipients

Avelox Film-coated Tablets
- croscarmellose sodium
- lactose monohydrate
- magnesium stearate
- microcrystalline cellulose

The tablets are film-coated with a mixture of:
- ferric oxide red
- hypromellose 15cP
- macrogol 4000titanium dioxide.

Avelox IV 400 Solution for infusion
- sodium chloride
- hydrochloric acid 1N
- sodium hydroxide solution 2N
- water for injection
6.2 Incompatibilities

Avelox IV 400 Solution for Infusion

The following infusions were found to be incompatible with Avelox solution for infusion:

- Sodium Chloride 10%
- Sodium Chloride 20%
- Sodium Hydrogen Carbonate 4.2%
- Sodium Hydrogen Carbonate 8.4%

6.3 Shelf life

Avelox Film-coated Tablets
5 years

Avelox IV 400 Solution for Infusion
Polyolefine flexibags – 3 years
Glass infusion bottles – 5 years

6.4 Special precautions for storage

Avelox Film-coated Tablets

Store at or below 25°C.

Avelox IV 400 Solution for Infusion

Store at or below 30°C. Do not store below 15°C. Do not refrigerate or freeze.

Store in the original container.

The product should be used immediately after opening.

6.5 Nature and contents of container <and special equipment for use, administration or implantation>

Nature and contents of container

Avelox Film-coated Tablets
Blister comprising polypropylene foil sealed with aluminium backing foil, in a cardboard outer. Pack of 5 tablets.

Avelox IV 400 Solution for Infusion
Polyolefine flexibags equipped with an administration port and overwrapped with an aluminium bag
or
Infusion bottles of colourless glass (type 2) sealed with PTFE-laminated chlorobutyl rubber stoppers.

**Instructions for use / handling**

*Avelox IV 400 Solution for Infusion*

At temperatures below 15°C precipitation may occur, which will re-dissolve at room temperature (15°C - 25°C). It is therefore recommended not to store the infusion solution at temperatures below 15°C.

The product should be inspected visually for particles prior to administration. Only clear solution free from particles should be used.

6.6 **Special precautions for disposal <and other handling>**

Any unused medicine or waste material should be disposed of in accordance with local requirements.

7 **MEDICINE SCHEDULE**

Prescription Medicine

8 **SPONSOR**
