NEW ZEALAND DATA SHEET

Biodone 2 mg/mL Oral solution
Biodone Forte 5 mg/mL Oral solution
Biodone Extra Forte 10 mg/mL Oral solution

1 PRODUCT NAME
Biodone, 2 mg/mL, Oral solution
Biodone Forte, 5 mg/mL, Oral solution
Biodone Extra Forte, 10 mg/mL, Oral solution

References to “Biodone” in this data sheet refer to all strengths.

2 QUALITATIVE AND QUANTITATIVE COMPOSITION
Methadone hydrochloride 2 mg/mL, 5 mg/mL, 10 mg/mL

For the full list of excipients, see section 6.1.

3 PHARMACEUTICAL FORM
Biodone is an oral solution containing methadone hydrochloride BP and is presented in 200 mL amber glass bottles with tamper-evident caps or in amber plastic bottles with an induction seal under the cap as tamper evidence. Biodone is yellow (due to sunset yellow), Biodone Forte is colourless and Biodone Extra Forte is red (due to permicol red, a diluted form of amaranth). There are no other additives or excipients in Biodone solutions.

4 CLINICAL PARTICULARS

4.1 Therapeutic indications
Oral Methadone is used in detoxification and maintenance treatment as a substitute for heroin or other morphine-like drugs to suppress the opiate-agonist abstinence syndrome in patients who are dependent on these drugs.

4.2 Dose and method of administration
Biodone is to be administered by the oral route only. Initial doses should be based on the individual's history of quantity, frequency and route of administration of opiates and should also take into account the person's hepatic and renal functioning. There may be some withdrawal symptoms not covered by the first dose. Initial doses will generally be in the range of 15-35 mg per day and should never be higher than 40 mg.

Subsequent dosage should be adjusted according to the requirements and response of the patient. Stabilisation of maintenance dosage usually occurs at 60-120 mg daily although a higher dosage is sometimes required. A single dose of Biodone daily usually adequately maintains the patient and there generally is no apparent advantage to divided doses. However, rapid metabolisers of methadone may not maintain adequate plasma methadone concentrations with usual dosing regimens. Maintenance dosage requirements should be reviewed regularly and reduced as indicated.

The dose of Biodone required is to be measured accurately, using a calibrated dropper or other appropriate method.
NEW ZEALAND DATA SHEET

Biodone 2 mg/mL Oral solution
Biodone Forte 5 mg/mL Oral solution
Biodone Extra Forte 10 mg/mL Oral solution

Biodone should be used in accordance with "Opioid Substitution Treatment, New Zealand Practice Guidelines" published by the Ministry of Health, February 2003. Substantial portions of this data sheet have been prepared from this publication, which may be downloaded from the publications page of www.moh.govt.nz.

4.3 Contraindications
Biodone is contraindicated in the following situations:

- individuals who are hypersensitive to methadone or to either of the colours sunset yellow (Biodone) or permicol red (Biodone Extra Forte) which are the only components in the formulations.
- in patients with respiratory depression, especially in the presence of cyanosis and excessive bronchial secretions.
- during an attack of bronchial asthma.
- in the presence of acute alcoholism, head injury and raised intracranial pressure.
- in individuals receiving monoamine oxidise inhibitors or within 14 days of stopping such treatment.
- in patients with ulcerative colitis, since it may precipitate toxic dilation or spasm of the colon.
- in patients with severe hepatic impairment as it may precipitate hepatic encephalopathy.
- in biliary and renal tract spasm.

4.4 Special warnings and precautions for use

Hazardous and harmful use
Biodone is subject to misuse, abuse and diversion, similar to opioids, legal or illicit. Monitor patients carefully for progression of opioid dependence and other drug use.

Respiratory Depression
Serious, life-threatening, or fatal respiratory depression has been reported with the use of methadone, even when used as recommended. It can occur at any time during the use of Biodone but the risk is greatest during initiation of therapy or following an increase in dose. Patients should be monitored closely for respiratory depression at these times.

Opioids can cause sleep-related breathing disorders including central sleep apnoea (CSA) and sleep-related hypoxemia. Opioid use increases the risk of CSA in a dose-dependent fashion. In patients who present with CSA, consider decreasing the opioid dosage using best practices for opioid taper.

Risks from concomitant use of benzodiazepines or other CNS depressants, including alcohol
Concomitant use of methadone and benzodiazepines or other CNS depressants (including other opioids, gabapentinoids, cannabis, sedatives, hypnotics, tricyclic antidepressants, antipsychotics, antihistamines, and centrally-active anti-emetics) increases the risk of adverse events and may result in sedation, respiratory depression, coma and death. Patients and their caregivers should be made aware of these symptoms. Patients and their
Serotonin syndrome
The development of serotonin syndrome, which is potentially life-threatening, has been reported with opioid use, including with methadone. This is mainly applicable to the use of methadone at higher doses such as in opioid substitution therapy. Serotonin syndrome has generally occurred when methadone was used concomitantly with other serotonergic drugs [see Section 4.5].

Serotonin syndrome may include mental status changes (e.g., agitation, hallucinations, coma, confusion), autonomic instability (e.g., tachycardia, labile blood pressure, hyperthermia, diaphoresis), neuromuscular abnormalities (e.g., hyperreflexia, incoordination, rigidity, tremor, myoclonus), and/or gastrointestinal symptoms (e.g., nausea, vomiting, diarrhoea).

If serotonin syndrome is suspected, a dose reduction or discontinuation of at least one of the serotonergic medicines being taken should be considered depending on the severity of symptoms.

Cardiac Repolarisation
Methadone should be administered with particular caution to patients at risk for development of prolonged QT interval.

In vitro and in vivo have demonstrated that methadone inhibits cardiac potassium channels and prolongs cardiac repolarisation (i.e. prolongs the QT interval). QT interval prolongation and serious arrhythmia (Torsades de Pointes) have been observed during treatment with methadone and appear to be more common with higher doses. Particular caution and careful monitoring is recommended in patients at risk of prolonged QT interval (e.g. cardiac hypertrophy, concomitant diuretic use, hypokalaemia, hypomagnesia), patients with a previous history of cardiac repolarisation prolongation, those taking medications affecting cardiac repolarisation or methadone metabolism, and in patients with an increased risk of arrhythmia [see Section 4.4 and Section 4.5]. Patients developing QT prolongation while on methadone treatment should be evaluated for modifiable risk factors, such as concomitant medications with cardiac effects, drugs which might cause electrolyte abnormalities and drugs which might act as inhibitors of methadone metabolism.

Dependence
In common with all opioids, prolonged use of methadone has the potential to produce dependence of the morphine type. The withdrawal symptoms are less intense but more prolonged than those produced by morphine or diamorphine. They develop more slowly and do not usually appear until 24 to 48 hours after the last dose. Discontinuation of methadone therapy should be carried out gradually in patients who may have developed physical dependence on the medicine so as to avoid precipitating withdrawal symptoms [see Section 4.8].
Phaeochromocytoma
Extreme caution should be exercised when administering methadone to patients with phaeochromocytoma, since aggravated hypertension has been reported in association with diamorphine.

Ambulatory Patients
Methadone should be used with caution in the presence of hypothyroidism, adrenocortical insufficiency, hypopituitarism, prostatic hypertrophy, shock and diabetes mellitus.

Accidental ingestion/exposure
Accidental ingestion or exposure of Biodone, especially by children, can result in a fatal overdose of methadone. Patients and their caregivers should be given information on safe storage and disposal of unused methadone [see Section 6.4 and Section 6.6].

Effects on Children
The fatal dose of methadone in children is 10 – 20 mg. Symptoms of opioid overdose in children are similar to those in adults, with pupillary miosis; however, the pupils may be normoreactive or, rarely, fixed and dilated. Infants may have drowsiness, coma and apnoea.

Children are usually, but not always, symptomatic. Known or suspected methadone intoxicated children should be hospitalised, since respiratory depression may be observed as long as 48 hours after ingestion. Successful resuscitation with a narcotic antagonist may be followed by relapse. Treatment must include establishment of an airway, maintenance of adequate respiratory ventilation, precise supportive care to maintain fluid and electrolyte balance, naloxone, emptying of upper and lower gastrointestinal tracts, and prevention of aspiration of gastric contents.

Use in the Elderly
Methadone has a long plasma half-life, which may lead to accumulation, particularly if renal function is impaired (see Renal Impairment).

In common with other opioids, methadone may cause confusion in this age group, therefore careful monitoring is advised.

Hepatic Impairment
Particular care should be taken when methadone is to be used in patients with hepatic impairment as these patients metabolise methadone more slowly than normal patients. Where not contraindicated methadone should be given at less than the normal recommended dose and the patient’s response used as a guide to further dosage requirements [see Section 4.3].

Renal Impairment
Biodone should be used with caution in patients with renal dysfunction.

Effects on laboratory tests
The serum BSP retention test may be increased (hepatotoxic effect or spasm of sphincter of
Oddi). Plasma cortisol may be increased in response to cold to an extent not seen in controls. An increase in the serum albumin, prolactin and immunoglobulin IgG levels may be seen as a response to chronic administration. A significant decrease in serum indocyanine green level has been observed in a small series of patients with normal liver function tests. PCO2 may be increased due to decreased pulmonary ventilation. Physiological changes in thyroid hormones may be seen – decrease in serum thyroxine (T4), a decrease in free thyroxine and an increase in tri-iodothyronine (T3).

### 4.5 Interaction with other medicines and other forms of interaction

The drugs listed below are known to affect methadone metabolism and should therefore be used with caution by those being treated with Biodone.

NOTE: Those with hepatitis C may have impaired liver function. This needs to be taken into account when the use of drugs metabolised by the liver is considered. The dose of paracetamol, for example, needs to be well within the standard 4 g per day.

<tr>
<td>Examples</td>
<td>Benzodiazepines and other sedatives/hypnotics, anxiolytics, tranquilizers, muscle relaxants, general anaesthetics, drugs with antihistamine-sedating actions such as antipsychotics, other opioids, alcohol.</td>
</tr>
</tbody>
</table>

### Serotonergic drugs

Co-administration of methadone with serotonergic drugs may increase the risk of serotonin syndrome, a potentially life-threatening condition [see Section 4.4].

Drugs that affect the serotonergic neurotransmitter system include selective serotonin reuptake inhibitors (SSRIs), serotonin and norepinephrine reuptake inhibitors (SNRIs), tricyclic antidepressants (TCAs), and monoamine oxidase inhibitors (MAOIs).
Use in pregnancy
Methadone maintenance therapy during pregnancy can improve the health of the mother and the chances of a full-term healthy baby. The main risk to the health of the foetus is for the pregnant woman to start and stop opiate use, particularly where this precipitates the opioid withdrawal syndrome. Women receiving Biodone during their pregnancy should be under the care of a specialist midwifery drug and alcohol service or a General Practitioner approved or authorised to prescribe controlled drugs for the treatment of dependence under the Misuse of Drugs Act 1975. The clinician should ensure that pregnant women have information regarding the effect of methadone maintenance therapy and illicit opioid use with nicotine, alcohol and other drug use on the foetus. Neonates should be observed closely for signs of respiratory depression if the mother has received methadone during labour.

Use in lactation
Methadone is transferred into breast milk at very low levels. Caution should be exercised when methadone is administered to a breastfeeding mother due to the risks of sedation and respiratory depression in the infant.

Breastfeeding mothers receiving methadone for opioid substitution treatment should be under specialist care from obstetric and paediatric staff with experience in monitoring for neonatal abstinence syndrome. The baby should be monitored for sedation and poor feeding particularly during the first three weeks of life. Breastfeeding mothers should receive specific information on how to identify respiratory depression and sedation in their babies and when it may be necessary to seek immediate medical care.

Breastfeeding mothers should be advised to wean slowly off breastfeeding when they decide to stop to reduce the possibility of withdrawal symptoms in the baby.

The evaluation of the risks and benefits of breastfeeding while on methadone for opioid substitution treatment should be done jointly by the prescriber and patient.

4.7 Effects on ability to drive and use machines
Patients who are well stabilised may continue to drive and operate machinery as part of their normal activities. If Biodone dosage has not been stabilised or is changed for any reason caution must be exercised due to the potential for increased drowsiness and other side effects.

4.8 Undesirable effects
The most frequently observed adverse reactions include lightheadedness, dizziness, sedation, nausea, vomiting, and sweating. These effects seem to be more prominent in ambulatory patients and in those who are not suffering severe pain. In such individuals, lower doses are advisable.

The major hazards of methadone are respiratory depression and, to a lesser degree, systemic hypotension. Respiratory arrest, shock, cardiac arrest, and death have occurred.
Other adverse reactions include the following:

Body as a whole: Weakness, oedema, headache

Cardiovascular: Arrhythmias, bigeminal rhythms, bradycardia, cardiomyopathy, ECG abnormalities, extrasystoles, flushing, heart failure, hypotension, palpitations, phlebitis, QT interval prolongation, syncope, T-wave inversion, tachycardia, torsades de pointes, ventricular fibrillation, ventricular tachycardia.

Endocrine: Hypogonadism

Gastrointestinal: Abdominal pain, anorexia, biliary tract spasm, constipation, dry mouth, glossitis.

Hematologic: Reversible thrombocytopenia has been described in opioid addicts with chronic hepatitis.

Metabolic: Hypokalaemia, hypomagnesaemia, weight gain, hypoglycaemia (frequency not known).

Musculoskeletal: Decreased muscle mass and strength, osteoporosis, and fractures.

Nervous system disorders: raised intracranial pressure, sedation.

Psychiatric: agitation, changes of mood, dependence, disorientation, dysphoria, euphoria, hallucinations, insomnia.

Renal: Antidiuretic effect, urinary retention or hesitancy.

Reproductive: Amenorrhoea, reduced libido and/ or potency, reduced ejaculate volume, reduced seminal vesicle and prostate secretions, decreased sperm motility, abnormalities in sperm morphology.

Respiratory: Pulmonary oedema, respiratory depression

Skin and subcutaneous tissue: Pruritus, other skin rashes, and rarely, hemorrhagic urticaria.

Maintenance on a stabilised dose: During prolonged administration of methadone, as in a methadone maintenance programme, constipation and sweating often persist and hypogonadism, decreased serum testosterone and reproductive effects are thought to be related to chronic opioid use.

**Reporting of suspected adverse reactions**

Reporting suspected adverse reactions after authorisation of the medicine is important. It allows continued monitoring of the benefit/risk balance of the medicine. Healthcare professionals are asked to report any suspected adverse reactions [https://nzphvc.otago.ac.nz/reporting/](https://nzphvc.otago.ac.nz/reporting/)
4.9 Overdose
For non-tolerant adults, doses of 50 mg or less have been known to be fatal, including doses taken orally. Potentially lethal overdoses of methadone can occur within 30 minutes to six hours after ingestion by non-tolerant or partially tolerant individuals.

Signs of methadone intoxication in an adult include pinpoint pupils, hypothermia, respiratory depression, bradycardia, pulmonary oedema (not always), hypotension, coma and seizures. Rhabdomyolysis, myoglobinuria, muscle necrosis and renal failure may occur secondary to methadone intoxication and may result from muscle damage related to prolonged coma and immobilisation or from a direct toxic effect of methadone.

Hypoglycaemia has been reported.

Rare events of leukoencephalopathy may occur in serious cases of overdosage.

To treat overdose, ensure that the airway is clear and perform emergency cardiopulmonary resuscitation as necessary. Take the person to hospital as soon as possible where treatment with an infusion of naloxone can be commenced. Overdose patients should remain in hospital for 24 – 72 hours due to methadone's long half-life.

For advice on the management of overdose please contact the National Poisons Centre on 0800 POISON (0800 764766).

5 PHARMACOLOGICAL PROPERTIES
5.1 Pharmacodynamic properties
Pharmacotherapeutic group: Drugs used in opioid dependence ATC Code: N07BC02

Methadone hydrochloride is an opiate agonist and exerts its principal pharmacological effect on the CNS and on the intestines. It interacts at specific receptor binding sites in the CNS and other tissues. Several subtypes of opiate receptors have been described including the μ type. Methadone interacts with the μ receptor to suppress opiate withdrawal. Methadone acts at several sites within the CNS involving several systems of neurotransmitter to produce analgesia, but the precise mechanism of action has not been fully elucidated. Methadone alters the perception of pain at the spinal cord and higher levels in the CNS and the patient’s emotional response to pain.

In addition to analgesia, the effects of Methadone on the CNS cause suppression of the cough reflex, respiratory depression, drowsiness, sedation, change in mood, euphoria, dysphoria, mental clouding, nausea and vomiting, and EEG changes. Methadone causes miosis which is antagonized by atropine.

Methadone increases smooth muscle tone in the urinary tract and induces spasms. In the urinary bladder, tone of the detrusor muscle is increased, possibly resulting in urinary urgency. Methadone also increases the tone of the vesical sphincter, which may make
urination difficult. These effects, in conjunction with the central effects of the drug on the release of vasopressin, may produce oliguria. Methadone has little cardiovascular effect when given in therapeutic doses to supine patients. When the patient assumes a “head-up” position, orthostatic hypotension and fainting may occur as a result of peripheral vasodilation. This peripheral vasodilation may be caused by opiate agonist-induced release of histamine or by depression of the vasomotor centre in the medulla. Methadone exerts endocrinologic effects, some of which may be related to CNS effects. Methadone generally simulates the release of vasopressin and inhibits the release of corticotropin, gonadotropins and thyrotropin.

5.2 Pharmacokinetic properties

Absorption
Methadone hydrochloride is readily absorbed after administration by mouth and has high oral bioavailability. Peak plasma concentrations occur at 4 hours, but this varies widely among individuals.

Distribution
Methadone undergoes considerable tissue distribution and protein binding is reported to be 60 to 90% with a1,-acid glycoprotein being the main binding protein in the plasma. The volume of distribution is 5 l/kg.

Metabolism
Metabolism to the major metabolite 2-ethylidine-1,5-dimethyl, 3,3-diphenylpyrrolidine and the minor metabolite 2-ethyl-3,3-diphenyl-5-methylpyrrolidine, both of them inactive, occurs in the liver. These metabolites are excreted in the faeces and urine together with unchanged methadone. Other metabolites, including methadol and normethadol (reported to be pharmacologically active), have also been described but account for a small proportion of the dose. The liver may also serve as a major storage site of unchanged methadone, which is taken up, bound non-specifically by the liver and released again mainly unchanged.

Excretion
Marked inter-individual variations in kinetics have been observed with methadone. Elimination half-lives vary considerably (a range of 15 to 60 hours has been reported) and careful adjustment of dosage is necessary with repeated administration, after which there is a gradual accumulation in the tissues.

Plasma concentrations have been found to vary widely during methadone maintenance therapy with large differences between patients and wide fluctuations in individual patients. Declining concentrations have been reported during methadone maintenance suggesting that tolerance occurs, possibly as a result of auto-induction of hepatic microsomal enzymes.

5.3 Preclinical safety data
No information held by the sponsor.
NEW ZEALAND DATA SHEET

Biodone 2 mg/mL Oral solution
Biodone Forte 5 mg/mL Oral solution
Biodone Extra Forte 10 mg/mL Oral solution

6 PHARMACEUTICAL PARTICULARS

6.1 List of excipients
Biodone - Sunset yellow FCF, Purified Water
Biodone Forte – Purified Water
Biodone Extra Forte – Amaranth, Purified Water

6.2 Incompatibilities
Biodone is incompatible with alkaline solutions, which cause precipitation.

6.3 Shelf life
Biodone – Amber glass bottle, 12 months from date of manufacture; Plastic HDPE bottle – 24 months from date of manufacture

Biodone Forte – Amber glass bottle, 12 months from date of manufacture; Plastic HDPE bottle – 24 months from date of manufacture

Biodone Extra Forte – Amber glass bottle, 12 months from date of manufacture, Plastic HDPE bottle – 24 months from date of manufacture

6.4 Special precautions for storage
Store Biodone in a cool, dry place below 25°C, in a controlled drug safe, but do not refrigerate. Pharmacists should emphasise the importance of storing takeaway doses in a cool place, out of sight from, and out of the reach of children. They should be locked away if possible. Always keep Biodone in the original container and do not use it if the expiry date on the container has run out.

6.5 Nature and contents of container
Biodone – 100 mL, 200 mL amber glass bottle; 200 mL Plastic HDPE bottle
Biodone Forte – 200 mL amber glass bottle; 200 mL Plastic HDPE bottle
Biodone Extra Forte – 200 mL amber glass bottle; 200 mL Plastic HDPE bottle

Not all pack sizes may be available.

6.6 Special precautions for disposal <and other handling>
Methadone hydrochloride is a controlled drug (B3) and must be stored in a controlled drug safe. All usage must be recorded in a controlled drug register.

Takeaway doses are to be dispensed as individual daily doses with each day’s dose packed in appropriately labelled bottles with child-resistant closures. The requirement for child resistant closures may be omitted if the prescriber has endorsed (or the pharmacist annotates) the prescription not to be dispensed in a container with a safety cap because of patient infirmity. Pharmacists should ensure that those receiving Biodone can open and close the CRCs correctly and are aware of the need for them.
