1 PRODUCT NAME

VEPESID® 50 mg and 100 mg capsules

2 QUALITATIVE AND QUANTITATIVE COMPOSITION

Pale pink, soft gelatin capsules containing 50 mg or 100 mg etoposide.

Excipients with known effect:
Each 50 mg capsule contains 0.47 mg of parahydroxybenzoate.
Each 100 mg capsule contains 0.61 mg of parahydroxybenzoate.

For the full list of excipients, see section 6.1.

3 PHARMACEUTICAL FORM

Soft gelatin capsule.

4 CLINICAL PARTICULARS

4.1 Therapeutic indications

VEPESID is indicated in the treatment of:

Small Cell Lung Cancer - VEPESID Capsules in combination with other approved chemotherapeutic agents as first-line treatment in patients with small cell lung cancer.

Hodgkin's Disease.

Malignant (non-Hodgkin's) lymphomas, especially of the histiocytic variety.

Acute non-lymphocytic leukaemia.

Testicular tumours in combination regimens for the treatment of refractory testicular tumours

4.2 Dose and method of administration

VEPESID should only be administered and monitored under the supervision of a qualified physician experienced in the use of anti-neoplastic medicinal products.

The dose of VEPESID capsules is based on the recommended dose with consideration given to the bioavailability of VEPESID capsules appearing to be dependent upon the dose administered. In view of significant intra-patient variability, dose adjustment may be required to achieve the desired therapeutic effect.

The usual dose of VEPESID capsules is 100-200 mg/m² (body surface area)/day, days 1 to 5 or 200 mg/m²/day, days 1, 3 and 5 every 3 to 4 weeks in combination with other agents approved for use in the disease to be treated. Dosage should be modified to take into account the myelosuppressive effects of other medications in the combination or the effects of prior X-ray therapy or chemotherapy which may have compromised bone marrow reserve.

Capsules should be taken on an empty stomach.

Elderly: No dosage adjustment is necessary; however, total dosage per course should not exceed
The usual number of treatment cycles (duration of treatment plus treatment-free interval) is 3 or 4. Doses may be increased or decreased and treatment cycles repeated, according to the individual's bone marrow reserve and tumour response. The optimum use of Vepesid is in combination with other chemotherapeutic agents.

**Renal Impairment:**

In patients with impaired renal function. The following initial dose modification should be considered based on measured creatinine clearance.

<table>
<thead>
<tr>
<th>Measured Creatinine Clearance</th>
<th>Dose of Etoposide</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;50 mL/min</td>
<td>100% of dose</td>
</tr>
<tr>
<td>15-50 mL/min</td>
<td>75% of dose</td>
</tr>
</tbody>
</table>

Subsequent dosing should be based on patient tolerance and clinical effect. Data are not available in patients with creatinine clearance <15 mL/min and further dose reduction should be considered in those patients.

**4.3 Contraindications**

Vepesid is contraindicated in patients with severe hepatic dysfunction or in those patients who have demonstrated a previous hypersensitivity to etoposide or any component of the formulation.

**4.4 Special warnings and precautions for use**

Vepesid should be administered under the supervision of a qualified physician experienced in the use of cancer chemotherapeutic agents. Severe myelosuppression with resulting infection or bleeding may occur.

Fatal myelosuppression has been reported following etoposide administration.

Patients being treated with VEPESID must be observed for myelosuppression carefully and frequently both during and after therapy. Dose limiting bone marrow suppression is the most significant toxicity associated with VEPESID therapy. Therefore, the following studies should be obtained at the start of therapy and prior to each subsequent dose of VEPESID: platelet count, haemoglobin, white blood cell count and differential.

The occurrence of a platelet count below 50,000/mm³ or an absolute neutrophil count below 500/mm³ is an indication to withhold further therapy until the blood counts have sufficiently recovered.

Physicians should be aware of the possible occurrence of an anaphylactic reaction manifested by chills, fever, tachycardia, bronchospasm, dyspnoea and hypotension which can be fatal. Treatment is symptomatic. Administration of VEPESID should be terminated immediately, followed by the administration of pressor agents, corticosteroids, antihistamines, or volume expanders at the discretion of the physician.
General

In all instances where the use of VEPESID is considered for chemotherapy, the physician must evaluate the need and usefulness of the medicine against the risk of adverse reactions. Most such adverse reactions are reversible if detected early. If severe reactions occur, the medicine should be reduced in dosage or discontinued and appropriate corrective measures should be taken according to the clinical judgment of the physician. Reinstigation of VEPESID therapy should be carried out with caution, and with adequate consideration of the further need for the medicine and alertness as to possible recurrence of toxicity. Patients with low serum albumin may be at increased risk for etoposide – associated toxicities.

Carcinogenesis

Carcinogenicity tests with VEPESID have not been conducted in laboratory animals. Given its mechanism of action, it should be considered a possible carcinogen in humans (see 4.8 Undesirable effects).

Vepesid has been shown to be mutagenic in in vitro test systems.

The occurrence of acute leukaemia, which can occur with or without a preleukaemic phase, has been reported rarely in patients treated with VEPESID in association with other antineoplastic drugs. Neither the cumulative risk, nor the predisposing factors related to the development of secondary leukaemia are known. The roles of both administration schedules and cumulative doses of etoposide have been suggested but have not been clearly defined.

An 11q23 chromosome abnormality has been observed in some cases of secondary leukaemia in patients who have received epipodophyllotoxins. This abnormality has also been seen in patients developing secondary leukaemia after being treated with chemotherapy regimens not containing epipodophyllotoxins and in leukaemia occurring de novo. Another characteristic that has been associated with secondary leukaemia in patients who have received epipodophyllotoxins appears to be a short latency period, with average median time to development of leukaemia being approximately 32 months.

Paediatric Use

Safety and effectiveness in paediatric patients have not been systematically studied.

Renal impairment

In patients with moderate (CrCl = 15 to 50 mL/min), or severe (CrCl < 15 mL/min) renal impairment undergoing haemodialysis, etoposide should be administered at a reduced dose. Haematological parameters should be measured and dose adjustments in subsequent cycles considered based on haematological toxicity and clinical effect in moderate and severe renal impaired patients.

Hepatic impairment

Patients with impaired hepatic function should regularly have their hepatic function monitored due to the risk of accumulation.

Tumour lysis syndrome

Tumour lysis syndrome (sometimes fatal) has been reported following the use of etoposide in association with other chemotherapeutic drugs. Close monitoring of patients is needed to detect early signs of tumour lysis syndrome, especially in patients with risk factors such as bulky treatment-sensitive tumours, and renal insufficiency. Appropriate preventive measures should also be considered in patients at risk of this complication of therapy.

Vaccinations
Concomitant use of VEPESID with a live virus vaccine may potentiate the replication of the vaccine virus and/or may increase the adverse reaction of the vaccine virus because normal defence mechanisms may be suppressed by VEPESID. Vaccination with a live vaccine in a patient taking VEPESID may result in severe infection. Patient’s antibody response to vaccines may be decreased. The use of live vaccines should be avoided and individual specialist advice sought.

Other warnings

VEPESID contains sodium ethyl parahydroxybenzoate and sodium propyl parahydroxybenzoate which may cause allergic reactions (possibly delayed).

4.5 Interaction with other medicines and other forms of interaction

Phenylbutazone, sodium salicylate and aspirin at concentrations achieved in vivo displace protein-bound etoposide.

High dose ciclosporin, resulting in concentrations above 2000 ng/mL, administered with oral etoposide has led to an 80% increase in etoposide exposure (AUC) with a 38% decrease in total body clearance of etoposide compared to etoposide alone.

Concomitant cisplatin therapy is associated with reduced total body clearance of etoposide.

Concomitant phenytoin therapy is associated with increased VEPESID clearance and reduced efficacy, and other antiepileptic therapy may be associated with increased VEPESID clearance and reduced efficacy.

Co-administration of antiepileptic drugs and VEPESID can lead to decreased seizure control due to pharmacokinetic interactions between the drugs.

Concomitant warfarin therapy may result in elevated international normalized ratio (INR). Close monitoring of INR is recommended.

Cross resistance between anthracyclines and etoposide has been reported in preclinical experiments.

There is increased risk of fatal systemic vaccine disease with the concomitant use of live vaccines. Live vaccines are not recommended in immunosuppressed patients. (see 4.4 Special warnings and precautions for use).

Prior or concurrent use of other drugs with similar myelosuppressive action as etoposide may be expected to have additive or synergetic effects.

4.6 Fertility, pregnancy and lactation

Pregnancy

VEPESID can cause foetal harm when administered to pregnant women. VEPESID has been shown to be teratogenic in mice and rats. There are no adequate and well-controlled studies in pregnant women. If this medicine is used during pregnancy, or if the patient becomes pregnant while receiving this medicine, the patient should be apprised of the potential hazard to the foetus. Women of childbearing potential should be advised to avoid becoming pregnant.

Given the mutagenic potential of VEPESID, an effective contraception is required for both male and female patients during treatment and up to 6 months after ending treatment. Genetic consultation is recommended if the patient wishes to have children after ending the treatment. As VEPESID may decrease male fertility, preservation of sperm may be considered for the purpose of later fatherhood.

Breast feeding

It is not known whether this drug is excreted in human milk. Because many drugs are excreted in human milk and because of the potential for serious adverse reactions in nursing infants from VEPESID, a
decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

4.7 Effects on ability to drive and use machines

No studies on the effects on the ability to drive and use machines have been performed. Etoposide may cause adverse reactions that affect the ability to drive and use machines such as fatigue, somnolence, nausea, vomiting, cortical blindness, hypersensitivity reactions with hypotension. Patients who experience such adverse reactions should be advised to avoid driving or using machines.

4.8 Undesirable effects

In the paragraphs below the incidences of adverse reactions, given as the mean percent, are derived from studies that utilised single agent VEPESID therapy.

Haematological Toxicity

Myelosuppression with fatal outcome has been reported following etoposide administration. Myelosuppression is most often dose-limiting, with granulocyte nadirs occurring 7 to 14 days, and platelet nadirs occurring 9 to 16 days, after administration. Bone marrow recovery is usually complete by day 20, and no cumulative toxicity has been reported.

Leukopenia and severe leukopenia (less than 1,000 cell/mm³) were observed in 60 to 91 percent and 7 to 17 percent, respectively, of patients treated with single agent VEPESID. Thrombocytopenia and severe thrombocytopenia (less than 50,000 platelets/mm³) were seen in 28 to 41 percent and 4 to 20 percent, respectively, of this same group of patients. The occurrence of acute leukaemia with or without a preleukaemic phase has been reported in patients treated with VEPESID in association with other antineoplastic agents.

Infection and haemorrhage have been reported.

Gastrointestinal Toxicity

Nausea and vomiting are the major gastrointestinal toxicities and can usually be controlled by antiemetic therapy. Anorexia, stomatitis and diarrhoea have also been reported. Mild to severe mucositis/esophagitis may occur.

Alopecia

Reversible alopecia, sometimes progressing to total baldness, has been observed in up to 66% of patients.

Allergic Reactions

Anaphylactic-like reactions manifested by chills, fever, tachycardia, bronchospasm, dyspnoea and hypotension have occurred very rarely in patients treated with oral capsules. These reactions have usually responded promptly to the administration of pressor agents, corticosteroids, antihistamines or volume expanders as appropriate.

Neuropathy

The use of VEPESID has been reported to cause peripheral neuropathy in 0.7% of patients.

Other Toxicities

The following reactions have been rarely reported: interstitial pneumonitis/pulmonary fibrosis, seizures (occasionally associated with allergic reactions), central nervous system toxicity (somnolence and fatigue), liver toxicity, alanine aminotransferase increased, alkaline phosphatase increased, aspartate amino transferase increased, bilirubin increased, aftertaste, fever, Stevens-Johnson syndrome, toxic epidermal necrolysis (one fatal case has been reported), rash, pigmentation, pruritus, urticaria, abdominal pain, constipation, dysphagia, asthenia, malaise transient cortical blindness, a single report

Vepesid v9.0
of radiation recall, dermatitis and optic neuritis.

**VEPESID** was reported leading to infertility.

### Metabolic Complications

Tumour lysis syndrome (sometimes fatal) has been reported following the use of **VEPESID** in association with other chemotherapeutic drugs.

Myocardial infarction and arrhythmia have been reported.

### Reporting of suspected adverse reactions

Reporting suspected adverse reactions after authorisation of the medicine is important. It allows continued monitoring of the benefit/risk balance of the medicine. Healthcare professionals are asked to report any suspected adverse reactions [https://nzphvc.otago.ac.nz/reporting](https://nzphvc.otago.ac.nz/reporting)

### 4.9 Overdose

Mucositis, myelotoxicity and metabolic acidosis and cases of serious hepatic toxicity have been reported in patients receiving higher than recommended doses of etoposide.

For advice on the management of overdose please contact the National Poisons Centre on 0800 POISON (0800 764766).

### 5 PHARMACOLOGICAL PROPERTIES

#### 5.1 Pharmacodynamic properties

Pharmacotherapeutic group: Cytostatics, plant alkaloids and other natural products, podophyllotoxin derivatives, ATC code: L01CB01.

**VEPESID**, a ready-to-use dosage form of etoposide (VP-16-213), a semi-synthetic derivative of podophyllotoxin, is an anti-neoplastic drug for oral use, which can be used alone or in combination with other oncolytic drugs.

**VEPESID** has been shown to cause metaphase arrest in chick fibroblasts. Its main effect, however, appears to be at the G₂ portion of the cell cycle in mammalian cells. Two different dose-dependent responses are seen. At high concentrations (10 µg/mL or more), lysis of cells entering mitosis is observed. At low concentrations (0.3 to 10 µg/mL), cells are inhibited from entering prophase. It does not interfere with microtubular assembly. The predominant macromolecular effect of **VEPESID** appears to be the induction of DNA strand breaks by an interaction with DNA-topoisomerase II or the formation of free radicals.

#### 5.2 Pharmacokinetic properties

On intravenous administration, the disposition of etoposide is best described as a biphasic process with a distribution half-life of about 1.5 hours and terminal elimination half-life ranging from 4 to 11 hours. Total body clearance values range from 33 to 48 mL/min or 16 to 36 mL/min/m² and, like the terminal elimination half-life, are independent of dose over a range 100-600 mg/m². Over the same dose range, the areas under the plasma concentration vs. time curves (AUC) and the maximum plasma concentration (Cₘₐₓ) values increase linearly with dose. Etoposide does not accumulate in the plasma following daily administration of 100 mg/m² for 4 to 6 days.

The mean volumes of distribution at steady state fall in the range of 18 to 29 litres or 7 to 17/m². Etoposide enters the CSF poorly. Although it is detectable in CSF and intracerebral tumours, the concentrations are lower than in extracerebral tumours and in plasma. Etoposide concentrations are higher in normal lung than in lung metastases and are similar in primary tumours and normal tissues of
the myometrium. *In vitro*, etoposide is highly protein bound (97%) to human plasma proteins.

After intravenous administration of 3H-etoposide (70-290 mg/m²), mean recoveries of radioactivity in the urine range from 42 to 67%, and faecal recoveries range from 0 to 16% of the dose. Less than 50% of an intravenous dose is excreted in the urine as etoposide with mean recoveries of 8 to 35% within 24 hours.

In children, approximately 55% of the dose is excreted in the urine as etoposide in 24 hours. The mean renal clearance of etoposide is 7 to 10 mL/min/m² or about 35% of the total body clearance over a dose range of 80 to 600 mg/m². Etoposide, therefore, is cleared by both renal and non-renal processes, i.e. metabolism and biliary excretion. The effect of renal disease on plasma etoposide clearance is not known.

Biliary excretion appears to be a minor route of etoposide elimination. Only 6% or less of an intravenous dose is recovered in the bile as etoposide. Metabolism accounts for most of the non-renal clearance of etoposide. The major urinary metabolite of etoposide in adults and children is the hydroxy acid [4'-demethyl epipodophyllinic acid-9-(4, 6-0-ethylidene-ß-D-glucopyranoside)], formed by opening of the lactone ring. It is also present in human plasma, presumably as the trans isomer. Glucuronide and/or sulphate conjugates of etoposide are excreted in human urine and represent 5 to 22% of the dose.

After oral capsule administration, the C_max and AUC values exhibit marked intra- and inter-subject variability. This results in variability in the estimates of the absolute oral bioavailability of etoposide oral capsules.

The overall mean value of oral capsule bioavailability is approximately 50% (range 25-75%).

A recent study concluded that the mean bioavailability of a 100 mg oral dose was 76 ± 22%. A 400 mg dose of VEPESID capsules proved to be 48 ±18% bioavailable.

There is no evidence of a first-pass effect for etoposide. For example, no correlation exists between the absolute oral bioavailability of etoposide capsules and non-renal clearance. No evidence exists for any other differences in etoposide metabolism and excretion after administration of oral capsules as compared to intravenous infusion.

In adults, the total body clearance of etoposide is correlated with creatinine clearance, low serum albumin concentration, and non-renal clearance. In adult cancer patients with liver dysfunction, total body clearance of etoposide is not reduced. Patients with impaired renal function receiving etoposide have exhibited reduced total body clearance, increased AUC and lower steady state volume of distribution (See [4.2 Dose and method of administration](#)). In children, elevated SGPT levels are associated with reduced drug total body clearance. Prior use of cisplatin may also result in a decrease of etoposide total body clearance in children. Further study is required to determine if dosage modification is required in patients with decreased etoposide body clearance.

### 5.3 Preclinical safety data

Cross resistance between anthracyclines and etoposide has been reported in preclinical experiments. VEPESID was subjected to a teratology study in SPF rats at doses of 0.13, 0.4, 1.2 and 3.6 mg/kg /day administered intravenously on Days 6 to 15 of gestation. VEPESID caused a dose-related maternal toxicity, embryotoxicity and teratogenicity at dose levels of 0.4 mg/kg/day and higher. Embryonic resorptions were 90 and 100 percent at the two highest dosages. At 0.4 and 1.2 mg/kg, foetal weights were decreased and foetal abnormalities occurred including major skeletal abnormalities, encephalohy and anencephaly and anophthalma. Even at the lowest dose tested, 0.13 mg/kg, a significant increase in retarded ossification was observed.

A study of Swiss-Albino mice given a single intraperitoneal injection of VEPESID at dosages of 1.0, 1.5 and 2 mg/kg on Days 6, 7 and 8 of gestation disclosed dose-related embryotoxicity, various cranial abnormalities and major skeletal malformations.

Vepesid v9.0
6 PHARMACEUTICAL PARTICULARS

6.1 List of excipients

Other ingredients: citric acid, glycerin, purified water and polyethylene glycol 400. The soft gelatin capsules contain gelatin, glycerin, sorbitol, purified water and parabens (ethyl and propyl) with the following dye system: iron oxide (red) and titanium dioxide, the capsules are printed with edible ink.

6.2 Incompatibilities

None Stated.

6.3 Shelf life

VEPESID Capsules: 36 months.

6.4 Special precautions for storage

Store at or below 25°C.

6.5 Nature and contents of container

VEPESID 100 mg capsules are packed in blisters of 10 capsules, each capsule containing 100 mg etoposide.

VEPESID 50 mg capsules are packed in blisters of 20 capsules, each capsule containing 50 mg etoposide.

6.6 Special precautions for disposal

Procedures for proper handling and disposal of anti-cancer agents should be considered. Several guidelines on this subject have been published. Any unused product should be disposed of in accordance with local requirements.
